## Chapter 7

# Separation Axioms

### 7.1 Compactness and Separation Axioms

**Proposition 7.1.** *Let  $X$  be a  $T_2$  space,  $x \in X$  and  $F$  is a compact subset of  $X$  not containing  $x$ . Then there exist opensets  $U, V$  such that  $x \in U, F \subset V$  &  $U \cap V = \phi$ .*

**Corollary 7.1.1.** *A compact subset in a  $T_2$  space is closed.*

**Corollary 7.1.2.** *Every map from a compact space into a  $T_2$  space is closed. And its range is a quotient space of the domain.*

**Corollary 7.1.3.** *A continuous bijection from a compact space onto a  $T_2$  space is a homeomorphism.*

**Corollary 7.1.4.** *Every continuous, one-to-one function from a compact space into a  $T_2$  space is an embedding.*

**Theorem 7.2.** *Every compact  $T_2$  space is a  $T_3$  space.*

**Proposition 7.3.** *Let  $X$  be a regular space,  $C$  a closed subset of  $X$  and  $F$  a compact subset of  $X$ , such that  $C \cap F = \phi$ . Then there exist open sets  $U, V$  such that  $C \subset U, F \subset V$  and  $U \cap V = \phi$ .*

**Theorem 7.4.** *Every regular, Lindeloff space is normal.*

**Corollary 7.4.1.** *Every regular, second countable space is normal.*

**Corollary 7.4.2.** *Every compact  $T_2$  space is  $T_4$ .*

### 7.2 The Urysohn Characterisation of Normality

**Proposition 7.5.** *Let  $A, B$  be subsets of a space  $X$  and suppose there exists a continuous function  $f : X \rightarrow [0, 1]$ , such that  $f(x) = 0, \forall x \in A$  and  $f(x) = 1, \forall x \in B$ . Then there exists disjoint open sets  $U, V$  such that  $A \subset U$  and  $B \subset V$ .*

**Corollary 7.5.1.** *If  $X$  has the property that for any disjoint closed subsets  $A, B$  of  $X$ , there exists a continuous function  $f : X \rightarrow [0, 1]$  such that  $f(x) = 0, \forall x \in A$  and  $f(x) = 1, \forall x \in B$ , then  $X$  is normal.*

**Theorem 7.6.** *A topological space  $X$  is normal iff it has the property that for every mutually disjoint, closed subsets  $A, B$  of  $X$ , there exists a continuous function  $f : X \rightarrow [0, 1]$  such that  $f(x) = 0$  for all  $x \in A$  and  $f(x) = 1$  for all  $x \in B$ .*

**Lemma 7.7.** *Let  $f : X \rightarrow [0, 1]$  be continuous. For each  $t \in \mathbb{R}$  let  $F_t = \{x \in X : f(x) < t\}$ . Then the indexed family  $\{F_t : t \in \mathbb{R}\}$  has the following properties*

1.  $F_t$  is an open subset of  $X$  for each  $t \in \mathbb{R}$
2.  $F_t = \emptyset$  for  $t < 0$
3.  $F_t = X$  for  $t > 1$
4. For any  $s, t \in \mathbb{R}$ ,  $s < t \implies \overline{F_s} \subset F_t$ .

Moreover, for each  $x \in X$ ,  $f(x) = \inf\{t \in \mathbb{Q} : x \in F_t\}$ .

**Lemma 7.8.** *Let  $X$  be a topological space and suppose  $\{F_t : t \in \mathbb{Q}\}$  is a family of sets in  $X$  such that*

1.  $F_t$  is open in  $X$  for each  $t \in \mathbb{Q}$
2.  $F_t = \emptyset$  for  $t \in \mathbb{Q}$ ,  $t < 0$
3.  $F_t = X$  for  $t \in \mathbb{Q}$ ,  $t > 1$
4.  $\overline{F_s} \subset F_t$  for  $s, t \in \mathbb{Q}$ ,  $s < t$

For  $x \in X$ , let  $f(x) = \inf\{t \in \mathbb{Q} : x \in F_t\}$ . Then  $f$  is a continuous real-valued function on  $X$  and it takes values in the unit interval  $[0, 1]$ .

**Corollary 7.8.1.** *All  $T_4$  spaces are completely regular and hence Tychonoff.*

*Proof.* Let  $x \in X$  and  $D$  be closed subset not containing  $x$ . We have  $X$  is a  $T_4$  space. Therefore  $X$  is  $T_1$  as well as normal. Now the singleton set,  $\{x\}$  is closed, since  $X$  is a  $T_1$  space. And by Urysohn's lemma for disjoint, closed subsets  $\{x\}, D$  there exists a continuous, real-valued function  $f : X \rightarrow [0, 1]$  such that  $f(x) = 0$  and  $f(y) = 1$  for all  $y \in D$ . Therefore the space  $X$  is completely regular and hence Tychonoff.  $\square$

**Remark** (Urysohn function). *The function whose existence is asserted by Urysohn's lemma is called a Urysohn function*

### 7.3 Tietze Characterisation of Normality

**Proposition 7.9.** *Let  $A$  be a subset of a space  $X$  and let  $f : A \rightarrow \mathbb{R}$  be continuous. Then any two extensions of  $f$  to  $X$  agree on  $\overline{A}$ . In other words, if at all an extension of  $f$  exists its values on  $\overline{A}$  are uniquely determined by values of  $f$  on  $A$ .*

**Proposition 7.10.** *Suppose a topological space  $X$  has the property that for every closed subset  $A$  of  $X$ , every continuous real valued function on  $A$  has a continuous extension to  $X$ . Then  $X$  is normal.*

**Definitions 7.11** (Pointwise Convergence). *Let  $X$  be a topological space and  $(Y, d)$  a metric space. Then a sequence of functions  $\{f_n\}$  from  $X$  to  $Y$  converges pointwise to  $f$  if for every  $x \in X$  the sequence  $\{f_n(x)\}$  converges to  $f(x)$  in  $Y$ .*

*In other words, given a very small value,  $\epsilon > 0$ , there exists some  $\delta > 0$  such that for every  $x \in X$  there exists  $N_x \in \mathbb{N}$ . This  $N_x$  may be different for different values of  $x$  and for every  $n > N_x$ ,  $d(f(x), f_n(x)) < \delta$ .*

**Definitions 7.12** (Uniform Convergence). *Let  $X$  be a topological space and  $(Y, d)$  a metric space. Then a sequence of functions  $\{f_n\}$  from  $X$  to  $Y$  converges uniformly to  $f$  if given a small  $\epsilon > 0$ , there exists  $\delta > 0$  such that there exists  $N \in \mathbb{N}$ . This  $N$  is independent of the value of  $x$  and for every  $n > N$ ,  $d(f(x), f_n(x)) < \delta$ .*

**Proposition 7.13.** *Let  $X$ ,  $(Y, d)$ ,  $\{f_n\}$  and  $f$  be as above and suppose  $\{f_n\}$  converges to  $f$  uniformly. If each  $f_n$  is continuous, then  $f$  is continuous.*

**Definitions 7.14** (Uniform Convergence of Series). *Let  $X$  be a topological space and  $(Y, d)$  be a metric space. Then a series of function  $\sum_{n=1}^{\infty} f_n$  converges uniformly to  $f$  if the sequence of partial sums converges uniformly to  $f$ .*

*In other words, let  $g_m = \sum_{n=1}^m f_n$ . Then  $\sum_{n=1}^{\infty} f_n$  converges to  $f$  uniformly if the sequence of partial sums  $\{g_m\}$  converges to  $f$  uniformly.*

**Proposition 7.15.** *Let  $\sum_{n=1}^{\infty} M_n$  be a convergent series of non-negative real numbers. Suppose  $\{f_n\}$  is a sequence of real valued functions on a space  $X$  such that for each  $x \in X$  and  $n \in \mathbb{N}$ ,  $|f_n(x)| \leq M_n$ . Then the series  $\sum_{n=1}^{\infty} f_n$  converges uniformly to a real valued function on  $X$ .*

## Nets and Filters

### 10.1 Definition and Convergence of Nets

**Definitions 10.1** (Directed Set). [Joshi, 1983, 10.1.1]

A directed set  $D$  is a pair  $(D, \geq)$  where  $D$  is a nonempty set and  $\geq$  is a binary relation on  $D$  such that

1. The relation ‘follows’ ( $\geq$ ) is transitive. ie,  $m \geq n, n \geq p \implies m \geq p$
2. The relation ‘follows’ ( $\geq$ ) is reflexive. ie, For every  $m \in D$ ,  $m \geq m$
3. For any  $m, n \in D$ , there exists  $p \in D$  such that  $p \geq m$  and  $p \geq n$ .

**sequence in a set**  $X$  is a function  $f$  from the set of all integers into  $X$ .

**Definitions 10.2** (Net). [Joshi, 1983, 10.1.2]

A net in a set  $X$  is a function  $S$  from a directed set  $D$  into the set  $X$ .

**Remark.** The set  $\mathbb{N}$  together with the relation ‘less than or equal to’ ( $\leq$ ) is a directed set. Clearly, the relation ‘less than or equal to’ is reflexive and transitive. And the third condition is true iff every finite subset  $E$  of  $D$  has an element  $p \in E$  such that  $p$  follows each element of  $E$ . This is a weaker notion compared to the well ordering principle<sup>1</sup> of the set of all integers. Thus  $\mathbb{N}$  is a directed set and every sequence in  $X$  is also a net in  $X$ .

**Remark** (Significance of Net). A net on a set is a generalisation of ‘a sequence on a set’ obtained by simplifying the domain of the sequence into a directed set. The notion directed set is derived by assuming a few properties of  $\mathbb{N}$ .

The convergence of sequence is not strong enough to characterise topologies as the limit of convergent sequences are unique for both Hausdorff and Co-countable spaces. The notion of Net allows us to differentiate between Hausdorff spaces from Co-countable spaces in terms of convergence of nets. The limit of a convergent net on a topological space is unique iff it is a Hausdorff space. ie, We have removed a few restrictions, so that we will have some convergent nets (which are obviously not sequences) with multiple limit points for Co-countable spaces.

---

<sup>1</sup>Well-ordering principle : Every subset of  $\mathbb{N}$  has a least element in it.

**Remark.** *Examples of Directed Sets*

1. Let  $X$  be a topological space and  $x \in X$ . Then the neighbourhood system  $\mathcal{N}_x$  is a directed set with the binary relation  $\subset$  (subset/inclusion).
  - (a) Let  $U, V, W$  be any three neighbourhoods of  $x \in X$  such that  $U \subset V$  and  $V \subset W$ . Then, clearly  $U \subset W$ .  
Therefore,  $U \geq V, V \geq W \implies U \geq W$ .
  - (b) Let  $U$  be any neighbourhood of  $x \in X$ , then  $U \subset U$ .  
Therefore,  $U \geq U$ .
  - (c) Let  $U, V$  be any two neighbourhoods of  $x \in X$ , then there exists their intersection  $W = U \cap V$ , which is a neighbourhood of  $x$ . Clearly  $W \subset U$  and  $W \subset V$ .  
Therefore  $\forall U, V \in \mathcal{N}_x, \exists W \in \mathcal{N}_x$  such that  $W \geq U$  and  $W \geq V$ .
2. Let  $\mathcal{P}$  be the set of all partitions on closed unit interval  $[0, 1]$ . A partition  $P \in \mathcal{P}$  is a refinement of  $Q \in \mathcal{P}$  if every subinterval in  $P$  is contained in some subinterval of  $Q$ . Then  $\mathcal{P}$  with the binary relation refinement is a directed set.

For example, let  $P = \{0, 0.3, 0.7, 1\}$ . Then the subintervals in  $P$  are  $[0, 0.3]$ ,  $[0.3, 0.7]$  and  $[0.7, 1]$ . Let  $Q = \{0, 0.3, 0.5, 1\}$  and  $R = \{0, 0.3, 0.5, 0.7, 1\}$ . Then  $R$  is a refinement of  $P$ , but  $Q$  is not a refinement of  $P$  since there is a subinterval  $[0.5, 1]$  in  $Q$  which is not properly contained in any subinterval of  $P$ . However,  $R$  is a refinement of  $Q$  as well.

- (a) Suppose  $P, Q, R$  are three partitions of  $[0, 1]$  such that  $P$  is a refinement of  $Q$  and  $Q$  is a refinement of  $R$ , then clearly  $P$  is a refinement of  $R$  since each subinterval of  $P$  is contained some subinterval of  $Q$ , which is contained in some subinterval of  $R$ .  
Therefore,  $P \geq Q, Q \geq R \implies P \geq R$
- (b) Suppose  $P$  is a partition of  $[0, 1]$ . Then trivially,  $P$  is a refinement of itself since every subinterval of  $P$  is contained in the same subinterval of  $P$ .  
Therefore,  $\forall P \in \mathcal{P}, P \geq P$
- (c) Suppose  $P, Q$  be any two partition of  $[0, 1]$ . Then  $R = P \cup Q$  is a refinement of both the partitions.  
Therefore  $\forall P, Q \in \mathcal{P}, \exists R \in \mathcal{P}$  such that  $R \geq P$  and  $R \geq Q$

**Remark.** *Examples of Nets*

1. Let  $X$  be a topological space and  $x \in X$ . Let  $\mathcal{N}_x$  be the set of all neighbourhoods of  $x$ . Let  $D = (\mathcal{N}_x, X)$  be the directed set given by  $(N, y) \in (\mathcal{N}_x, X)$  if  $N \in \mathcal{N}_x$  and  $y \in N$  and  $(N, y) \geq (M, z)$  if  $N \subset M$ . Then the function  $S : (\mathcal{N}_x, X) \rightarrow X$  given by  $S(N, y) = y$  is a net on  $X$ .

For example, let  $X = \{a, b, c, d\}$  and  $\mathcal{T} = \{\{a\}, \{a, b\}, \{a, b, c\}, \{a, b, c, d\}\}$ . Also let  $S : (\mathcal{N}_b, X) \rightarrow X$  defined by  $S(N, y) = y$ . Suppose  $C = \{a, b, c\}$ . Then  $C \in \mathcal{N}_b$ . ie,  $C$  is a neighbourhood of  $b$ . Then  $S(C, c) = c$ .

2. *Riemann Net* - Let  $D = (\mathcal{P}, \xi)$  where  $\mathcal{P}$  is the set of all partitions on  $[0, 1]$  and  $\xi$  is a finite sequence in  $[0, 1]$  such that consecutive terms belongs to consecutive subintervals of the partition. The set  $(\mathcal{P}, \xi)$  is directed set with  $\geq$  given by  $(P, \eta) \geq (Q, \psi)$  iff  $P$  is a refinement of  $Q$ .

For example, let  $P \in \mathcal{P}$  is given by  $P = \{ 0, 0.3, 0.7, 1 \}$  and  $\eta = \{ 0.2, 0.6, 0.9 \}$ . Then  $(P, \eta) \in (\mathcal{P}, \xi)$ .

Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be any function, then the function,

$$S : (\mathcal{P}, \xi) \rightarrow \mathbb{R} \text{ defined by } S(P, \eta) = \sum_{j=1}^k f(\eta_j)(a_j - a_{j-1})$$

where  $P = \{a_0, a_1, \dots, a_k\}$  is the Riemann Net with respect to the real function  $f$ .

For example, let  $f(x) = x^2$  and  $P, \eta$  are same as above example, then  $S(P, \eta) = 0.2^2(0.3 - 0) + 0.6^2(0.7 - 0.3) + 0.9^2(1 - 0.7) = 3.99$

**Definitions 10.3** (Convergence of a Net). [Joshi, 1983, 10.1.3]

A net  $S : D \rightarrow X$  converges to a point  $x \in X$  if for any nbd  $U$  of  $x$ , there exists  $m \in D$  such that  $n \in D, n \geq m \implies S(n) \in U$ . And  $x$  is a limit of the net  $S$ .

**Remark.** The choice of  $m$  depends on the choice of neighbourhood  $U$ .

$$S : D \rightarrow X, S \rightarrow x \iff (\forall U \in \mathcal{N}_x, \exists m_U \in D, \text{ such that } n \geq m_U \implies S(n) \in U)$$

**Theorem 10.4** (Net characterisation of Hausdorff space). [Joshi, 1983, 10.1.4]

A topological space is Hausdorff iff limits of all nets in it are unique.

*Proof.* Let  $X$  be a Hausdorff space. Suppose  $S : D \rightarrow X$  is net on  $X$  such that  $S$  converges to two distinct points  $x, y \in X$ . Since  $X$  is a Hausdorff space and  $x \neq y$ , there exists open sets  $U, V$  such that  $x \in U, y \in V, U \cap V = \emptyset$ .

The net  $S$  converges to  $x \in X$ , therefore  $\exists m_x \in D$  such that  $n \geq m_x \implies S(n) \in U$ . And, the net  $S$  converges to  $y \in X$ , therefore  $\exists m_y \in D$  such that  $n \geq m_y \implies S(n) \in V$ .

Since  $D$  is a directed set and  $m_x, m_y \in D$ , there exists  $p \in D$  such that  $p \geq m_x$  and  $p \geq m_y$ . Now,  $n \geq p \implies n \geq m_x, n \geq m_y$ , since  $\geq$  is transitive. (ie,  $n \geq p, p \geq m_x \implies n \geq m_x$ , and  $n \geq p, p \geq m_y \implies n \geq m_y$ ).

We have  $n \geq p \implies n \geq m_x$  and  $n \geq m_x \implies S(n) \in U$ . Therefore,  $n \geq p \implies S(n) \in U$ . Similarly,  $n \geq p \implies n \geq m_y \implies S(n) \in V$ . Therefore  $S(n) \in U \cap V$  which is a contradiction, since  $U \cap V = \emptyset$ . Therefore, if a net  $S$  converges to two points  $x, y$ , then  $x = y$ . That is, if a net  $S$  in a Hausdorff space  $X$  is convergent then its limit is unique.

Conversely, suppose that  $X$  is a topological space and every convergent net in  $X$  has a unique limit. Suppose  $X$  is not a Hausdorff space. Then there exists

at least two distinct points  $x, y \in X$  such that every neighbourhood of  $x$  intersects with every neighbourhood of  $y$ . Now consider the set  $D = \mathcal{N}_x \times \mathcal{N}_y$  and relation  $\geq$  on  $D$  such that  $(U_1, V_1) \geq (U_2, V_2)$  if  $U_1 \subset U_2$  and  $V_1 \subset V_2$ .

By the axiom of choice, a function  $S : D \rightarrow X$  such that  $S(U, V) \in U \cap V$  is well defined, since every nbd of  $x$  intersects every nbd of  $y$ . Thus,  $S$  is a net in  $X$ . We claim that  $S$  converges to both  $x$  and  $y$ .

Let  $U$  be a nbd of  $x$ . Then  $S(U', V') \in U' \cap V'$ . We have  $(U, X) \in D$  such that  $(U', V') \geq (U, X) \implies U' \subset U$ . Then,  $S(U', V') \in U' \cap V' \subset U \cap X = U$ . Thus, for any nbd  $U$  containing  $x$ , we have  $(U, X) \in D$  such that  $(U', V') \geq (U, X) \implies S(U', V') \in U$ . Therefore,  $S$  converges to  $x \in X$ .

Similarly, Let  $V$  be a nbd of  $y$ . Then for any nbd  $V$  containing  $y$ , we have  $(X, V) \in D$  such that  $(U', V') \geq (X, V) \implies S(U', V') \in V$ , since  $S(U', V') \in U' \cap V' \subset X \cap V = V$ . Therefore,  $S$  converges to  $y \in X$  as well, where  $x \neq y$ . This is a contradiction to the assumption that every convergent net in  $X$  has a unique limit. Therefore, for any two points  $x, y \in X$ , there should be some nbd of  $x$  that doesn't intersect some nbd of  $y$ . Therefore,  $X$  is a Hausdorff space.  $\square$

**Definitions 10.5** (Eventual Subset). [Joshi, 1983, 10.1.5]

A subset  $E$  of a directed set  $D$  is an eventual subset of  $D$  if there exists  $m \in D$  such that  $n \geq m \implies n \in E$ .

**Remark.** Let  $E$  be an eventual subset of  $D$  such that  $n \geq m \implies n \in E$ . Then  $p \in E \not\Rightarrow p \geq m$ . ie, Subset  $E$  may contain elements that doesn't follow the above  $m$ .

**Remark.** [Joshi, 1983, 10.1.6]

Let  $E$  be an eventual subset of  $D$ , then  $E$  is a directed set.

1.  $m, n, p \in E, m \geq n, n \geq p \implies m, n, p \in D, m \geq n, n \geq p \implies m \geq p$
2.  $m \in E \implies m \in D \implies m \geq m$
3.  $m, n \in E \implies m, n \in D \implies \exists p \in D$  such that  $p \geq m$  and  $p \geq n$ .  
 Since  $E$  is eventual,  $\exists m' \in D$  such that  $n' \geq m' \implies n' \in E$ .  
 Also,  $p, m' \in D, \exists p' \in D$  such that  $p' \geq p$  and  $p' \geq m'$ . (Condition 3)  
 Since,  $E$  is eventual subset of  $D$  with respect to  $m', p' \geq m' \implies p' \in E$ .  
 And since  $p' \geq p, p \geq m \implies p' \geq m$  and  $p' \geq p, p \geq n \implies p' \geq n$ .  
 Therefore  $\forall m, n \in E, \exists p' \in E$  such that  $p' \geq m$  and  $p' \geq n$ .

**Definitions 10.6** (Net eventually in  $A$ ). [Joshi, 1983, 10.1.5]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Then  $S$  is eventually in subset  $A$  of  $X$  if  $S^{-1}(A)$  is an eventual subset of  $D$ .

**Remark.** Let  $S : D \rightarrow X$  be a net in  $X$ . Then  $S$  converges to  $x \in X$  if  $S$  is eventually in each nbd  $U$  of  $x$ .

**Definitions 10.7** (Cofinal subset). [Joshi, 1983, 10.1.7]

A subset  $F$  of a directed  $D$  is a cofinal subset of  $D$  if for any  $m \in D$ , there exists  $n \in F$  such that  $n \geq m$ .

**Remark.** Let  $X$  be a topological space and  $x \in X$ . Let  $\mathcal{N}_x$  be the set of all neighbourhood of  $x$  and  $\mathcal{L}$  be a local base of  $X$  at  $x$ . We have,  $(\mathcal{N}_x, \supseteq)$  is a directed set where  $\forall U, V \in \mathcal{N}_x, U \supseteq V \iff U \subset V$ , then  $\mathcal{L}$  is cofinal in  $\mathcal{N}_x$ .

**Remark.** [Joshi, 1983, 10.1.8]

Let  $F$  be a cofinal subset of  $D$ , then  $F$  is a directed set.

1.  $m, n, p \in F, m \geq n, n \geq p \implies m, n, p \in D, m \geq n, n \geq p \implies m \geq p$
2.  $m \in F \implies m \in D \implies m \geq m$
3.  $m, n \in F \implies m, n \in D \implies \exists p \in D$  such that  $p \geq m$  and  $p \geq n$ .  
 Since  $E$  is cofinal,  $p \in D \implies \exists p' \in F$  such that  $p' \geq p$ .  
 And since  $p' \geq p, p \geq m \implies p' \geq m$  and  $p' \geq p, p \geq n \implies p' \geq n$ .  
 Therefore  $\forall m, n \in F, \exists p' \in F$  such that  $p' \geq m$  and  $p' \geq n$ .

**Definitions 10.8** (Net frequently in  $A$ ). [Joshi, 1983, 10.1.7]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Then  $S$  is frequently in subset  $B$  of  $X$  if  $S^{-1}(B)$  is a cofinal subset of  $D$ .

**Proposition 10.9.** [Joshi, 1983, 10.1.6]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Let  $E$  be an eventual subset of  $D$ . Then,  $S$  converges to  $x$  iff  $S|_E$  converges to  $x$ . [Joshi, 1983, 10.1.6]

*Proof.* Let  $S : D \rightarrow X$  be a net in  $X$ ,  $E$  be an eventual subset of  $D$ , and  $x \in X$ . Then,  $S|_E : E \rightarrow X$  is defined by  $n \in E \implies S|_E(n) = S(n)$

Suppose  $S$  converges to  $x$ . Let  $U$  be a nbd of  $x$ , then  $S$  is eventually in  $U$ . ie,  $S^{-1}(U)$  is an eventual subset of  $D$ . Then  $\exists m \in D$  such that  $n \geq m \implies n \in S^{-1}(U) \implies S(n) \in U$ . Since set  $E$  is eventual subset of  $D$ ,  $\exists m' \in D$  such that  $n \geq m' \implies n \in E$ .

Since  $E$  is a directed set,  $S|_E : E \rightarrow X$  is a net in  $X$ . And  $m, m' \in D \implies \exists p \in D$  such that  $p \geq m$  and  $p \geq m'$ . We have,  $p \geq m' \implies p \in E$ . And  $n \geq' p \implies n \geq p, p \geq m \implies n \geq m \implies S(n) \in U \implies S|_E(n) \in U$ . Therefore,  $n \geq' p \implies S|_E(n) \in U$ . Since  $U$  is arbitrary,  $S|_E$  converges to  $x$ .

Conversely, suppose that  $S|_E$  converges to  $x$ . Let  $U$  be a nbd of  $x$ , then  $S|_E$  is eventually in  $U$ . ie,  $S|_E^{-1}(U)$  is an eventual subset of  $D$ . ie,  $\exists m \in D$  such that  $n \geq m \implies n \in S|_E^{-1}(U) \implies S|_E(n) \in U \implies S(n) \in U$ . Therefore,  $n \geq m \implies S(n) \in U$ . Since,  $U$  is arbitrary,  $S$  converges to every nbd of  $x$ . ie,  $S$  converges to  $x$ .  $\square$

**Proposition 10.10.** [Joshi, 1983, 10.1.8]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Let  $F$  be a cofinal subset of  $D$ . If  $S$  converges to  $x$ , then  $S|_F$  converges to  $x$ .

*Proof.* Let  $S : D \rightarrow X$  be a net in  $X$  and  $S$  converges to  $x \in X$ . Also let  $F$  be a cofinal subset of  $D$ . Then  $S|_F$  is also a net in  $X$ , since  $(F, \geq')$  is a directed set where  $\forall m, n \in F, m \geq n \implies m \geq' n$ .

Since  $S$  converges to  $x$ , for any nbd  $U$  of  $x$ ,  $\exists m \in D$ , such that  $n \geq m \implies S(n) \in U$ . Since  $F$  is cofinal,  $\exists p \in F$  such that  $p \geq m$ . Thus  $n \geq' p \implies n \geq$

$p, p \geq m \implies n \geq m \implies S(n) \in U \implies S_{/F}(n) \in U$ . Therefore,  $\exists p \in F$  such that  $n \geq' p \implies S_{/F}(n) \in U$ . Since  $U$  is arbitrary,  $S_{/F}$  is eventually in every nbd of  $x$ . ie,  $S_{/F}$  converges to  $x$ .  $\square$

**Remark.** But converse of the above is not true.  $S_{/F}$  converges to  $x$  does not imply that  $S$  converges to  $x$ , since cofinal subset  $F$  not necessarily contain every element following a particular  $m$ .

**Definitions 10.11** (Cluster point). [Joshi, 1983, 10.1.9]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Then  $x \in X$  is a cluster point of  $S$ , if  $S$  is frequently in each nbd  $U$  of  $x$  in  $X$ .

**Proposition 10.12.** [Joshi, 1983, 10.1.10]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Then  $x \in X$  is a cluster point of  $S$ , if  $S_{/F}$  converges to  $x$  for some cofinal subset  $F$  of  $D$ .

*Proof.* Let  $S : D \rightarrow X$  be a net in  $X$  and  $(F, \geq')$  be a cofinal subset of  $(D, \geq)$ . Then  $S_{/F}$  is also a net in  $X$ . Suppose  $S_{/F}$  converges to  $x \in X$ . Let  $U$  be a nbd of  $x$ , then  $\exists m \in F$  such that  $n \geq' m \implies S_{/F}(n) \in U$ .

Let  $m' \in D$ . Then  $\exists p' \in F$  such that  $p' \geq m'$ , since  $F$  is a cofinal subset of  $D$ . We have,  $m, p' \in F$ , then  $\exists p \in F$  such that  $p \geq' m$  and  $p \geq' p'$ . Since  $F \subset D$ , we have  $p, m \in F \implies p, m \in D$  and  $p \geq' m \implies p \geq m$ .

Also  $p \geq' m \implies S_{/F}(p) \in U \implies S(p) \in U$ . Therefore,  $\forall m' \in D, \exists p \in D$  such that  $p \geq m'$  and  $S(p) \in U$ . Since  $U, m'$  are arbitrary,  $S$  is frequently in every nbd of  $x$ . ie,  $x$  is a cluster point of  $S$ .  $\square$

**Definitions 10.13** (Subnet). [Joshi, 1983, 10.1.11]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Then a net  $T : E \rightarrow X$  in  $X$ , is a subnet of  $S$  if there exists a function  $N : E \rightarrow D$  such that  $S \circ N = T$  and  $\forall m \in D, \exists p \in E$  such that  $n \geq' p \implies N(n) \geq m$ .

**Remark.** A net  $T : E \rightarrow X$  is a subnet of  $S : D \rightarrow X$  if  $\exists N : E \rightarrow D$  such that  $S \circ N = T$  and  $S$  is frequently in  $T(E)$ .

Let  $T : E \rightarrow X$  be a subnet of  $S : D \rightarrow X$  and  $A$  be a subset of  $X$ . If  $T$  eventually in  $A$ , then  $S$  is frequently in  $A$ .

**Proposition 10.14.** [Joshi, 1983, 10.1.12]

Let  $S : D \rightarrow X$  be a net in a topological space  $X$ . Then  $x \in X$  is a cluster point of  $S$  iff there exists a subnet of  $S$  which converges to  $x$ .

**Synopsis.** Let  $(D, \geq), (E, \geq')$  be two directed sets. And  $T : E \rightarrow X$  be a subnet of  $S : D \rightarrow X$ .

If  $T$  converges to  $x$ , then  $T$  is eventually in each nbd  $U$  of  $x$ . And since  $T$  is a subnet of  $S$ , there exists  $N : E \rightarrow D$  such that  $N(E)$  is a cofinal subset of  $D$ . Therefore,  $S$  is frequently in each nbd  $U$  of  $x$ . Thus,  $x$  is a cluster point of  $S$ .

If  $x$  is a cluster point of  $X$ , then  $S$  is frequently in every nbd of  $x$ . Let  $N : E \rightarrow D$  be  $N(n, U) = n$ . Construct a directed subset  $E$  of  $D \times \mathcal{N}_x$  such that  $(n, U) \in E \iff S(n) \in U$ . Now  $T$  is eventually in every nbd  $U$  of  $x$ , as those points with images outside  $U$  are removed by construction. Therefore,

*it is sufficient to show that  $T : E \rightarrow X$  is a subnet of the net  $S : D \rightarrow X$ . Clearly,  $E$  is a directed set and  $N : E \rightarrow D$  defined by  $N(n, U) = n$  satisfies both  $S \circ N = T$  and  $\forall n \in D, \exists p \in E$  such that  $m \geq p \implies N(m) \geq n$ .*

*Proof.* Let  $S : D \rightarrow X$  be a net in  $X$ . Suppose there exists a subnet  $T : E \rightarrow X$  that converges to  $x \in X$ . By the definition of subnet, we have  $\exists N : E \rightarrow D$  such that  $S \circ N = T$  and  $S$  is frequently in  $T(E)$ .

We have,  $T$  converges to  $x$ , thus for any neighbourhood  $U$  of  $x$ , there exists  $m' \in E$  such that  $n' \geq' m' \implies T(n') \in U$ .

Also we have,  $T$  is a subnet of  $S$ . Then  $\exists N : E \rightarrow D$  such that  $\forall m \in D, \exists p' \in E$  such that  $n' \geq' p' \implies N(n') \geq m$ .

Now, for any  $m \in D$ , we have  $m', p' \in E$ . Since  $E$  is a directed set, there exists  $n' \in E$  such that  $n' \geq' m'$  and  $n' \geq' p'$ .

Then,  $n' \geq m' \implies T(n') \in U$  and  $n' \geq' p' \implies N(n') \geq m$ .

Thus for any  $m \in D$ , there exists  $N(n') = n \in D$  such that  $S(n) = S(N(n')) = T(n') \in U$ .

Thus  $S$  is frequently in any neighbourhood  $U$  of  $x$ . Therefore,  $x$  is a cluster point of  $S$ .

Conversely, suppose that  $x$  is a cluster point of  $S$ . We have to construct a directed set  $(E, \geq')$  and a function  $N : E \rightarrow D$  such that  $T$  is a subnet of  $S$  and  $T$  converges to  $x$ .

Consider  $E = \{(n, U) \in D \times \mathcal{N}(x) : S(n) \in U\}$  and define  $\geq'$  by  $(n, U) \geq' (m, V)$  if  $n \geq m$  and  $U \subset V$ . Trivially,  $(n, U) \geq' (m, V) \geq' (p, W) \implies (n, U) \geq' (p, W)$  and  $(n, U) \geq' (n, U)$ . Also, for any  $(n, U), (m, V) \in E$ , we have  $n, m \in D$  and  $U, V \in \mathcal{N}(x)$ . Since  $D$  is a directed set,  $\exists p \in D$  such that  $p \geq n$  and  $p \geq m$ . Also, there exists  $q \in D$  such that  $S(q) \in U$  and  $q \geq' p$ , since  $S$  is frequently in every nbd  $U$  of  $x$ . And  $U \cap V \in \mathcal{N}(x)$  such that  $U \cap V \subset U$  and  $U \cap V \subset V$ . Thus  $\exists (q, U \cap V) \in E$  such that  $(q, U \cap V) \geq' (n, U)$  and  $(q, U \cap V) \geq' (m, V)$ . Therefore,  $(E, \geq')$  is a directed set.

Define  $N : E \rightarrow D$  by  $N(n, U) = n$ . Again for any  $(m, V) \in E$ , there exists  $m \in D$  such that  $(n, U) \geq' (m, V)$  implies there exists  $n \in D$  such that  $N(n, U) = n$  and  $n \geq m$ . Now, we have  $T : E \rightarrow X$  defined by  $T(n, U) = S(N(n, U)) = S(n)$ . Therefore,  $T$  is a subnet of  $S$ . Now every points in  $E$  are so defined that  $(n, U) \in E \implies S(n) \in U$ , we have  $T(n, U) \in U$ . Thus,  $T$  is eventually in every nbd of  $x$ . ie, subnet  $T$  of net  $S$  is convergent to  $x$ .  $\square$

**Remark.** • *Importance of Construction of  $E$*

*If  $x$  is a cluster point of a net  $S$  in  $X$ , then  $S$  is frequently in some cofinal subset of  $D$ . Thus, if we consider any cofinal subset  $D'$  of  $D$  which is a direct set with  $\geq$  restricted to  $D'$ . Then  $N : D' \rightarrow D$  defined by  $N(n) = n$  gives a subnet  $T : D' \rightarrow X$  of the net  $S$ . However, this subnet need not*

converge to  $x$ . The strongest statement, we can make on  $T$  is that ' $x$  is a cluster point of  $T$ ', since  $N : D \times \mathcal{N}(x) \rightarrow D$ ,  $N(n) = n$  is completely independent of  $U$ . This problem is overcome by constructing  $E$  which is dependent on each nbd  $U$  of  $x$ .

- Existence of  $q \in D$  such that  $q \geq' p$  and  $S(q) \in U$ . We have,  $p$  follows both  $n \& m$  and  $U \cap V$  is a subset of both  $U \& V$ . However, since  $S$  is only frequently in  $U$ ,  $p$  not necessarily be in  $U$ . But there is always someone following  $p$  which has its image in  $U$ . This  $q$  follows both  $n \& m$ , since  $\geq'$  is transitive.

# Chapter 11

## Compactness

### 11.1 Variations of Compactness

In this chapter, we have two other notions of compactness - countable compactness and sequential compactness.<sup>1</sup>

**Compact** A topological space is compact iff every open cover of it has a finite subcover. ([Joshi, 1983, 6.1.1]) [Heine-Borel]

**Countably Compact** A topological space is countably compact iff every countable, open cover of it has a finite subcover. [Joshi, 1983, 11.1.1]

**Sequentially Compact** A topological space is sequentially compact iff every sequence in it has a convergent subsequence. [Joshi, 1983, 11.1.8] [Bolzano-Weierstrass]

Countable compactness is a weaker notion compared to compactness.<sup>2</sup> However, sequentially compact and compact are not necessarily comparable.<sup>3</sup>

We have seen earlier that compactness has the following properties 1. compactness is weakly hereditary.[Joshi, 1983, 6.1.10] 2. compactness is preserved under continuous functions.[Joshi, 1983, 6.1.8] 3. every continuous real functions on compact space is bounded and attains its extrema.[Joshi, 1983, 6.1.6] 4. every continuous real function on a compact, metric space is uniformly continuous by Lebesgue covering lemma.[Joshi, 1983, 6.1.7]

Countably compact spaces, Sequentially compact spaces have all the four properties listed above.

#### 11.1.1 Countable compactness

##### Weakly hereditary property

A subspace  $(A, \mathcal{T}_A)$  being countably compact doesn't imply that  $(X, \mathcal{T})$  is countably compact. However, if  $(X, \mathcal{T})$  is a countably compact space and  $A$

---

<sup>1</sup>For  $\mathbb{R}$ , Compactness & Sequentially compactness are equivalent to the completeness axiom.

<sup>2</sup>Every compact space is countably compact.

<sup>3</sup> $\mathcal{T}_1, \mathcal{T}_2$  are non-comparable, if  $\mathcal{T}_1 \not\subset \mathcal{T}_2$  and  $\mathcal{T}_2 \not\subset \mathcal{T}_1$ . [Joshi, 1983, 4.2.1]

is a closed subset of  $X$ , then  $(A, \mathcal{T}_{/A})$  is also a countably compact space. In other words, countably compactness is weakly hereditary.

**Theorem 11.1.** *Countable compactness is weakly hereditary.* [Joshi, 1983, 11.1.3]

**Synopsis.** *Let  $A$  be a closed subset of countably compact space,  $X$ . If  $A$  has a countable open cover  $\mathcal{U}$ , then we can obtain a respective countable, open cover for  $X$  by attaching  $X - A$  to the extensions of members of  $\mathcal{U}$  to  $X$ . This cover has a finite subcover. Then restricting them to  $A$ , we get a finite subcover of  $\mathcal{U}$ .*

*Proof.* Suppose  $X$  is a countably compact space. And  $A$  is a closed subset of  $X$ . We need to show that  $A$  is countably compact. Without loss of generality,<sup>4</sup> assume that  $A$  is a proper subset of  $X$ . Then  $X - A$  is a non-empty, open subset of  $X$ .

Let  $\mathcal{U}$  be a countable open cover of  $A$ . Then  $\mathcal{U} = \{U_1, U_2, \dots\}$  where each element  $U_k \in \mathcal{U}$  is an open subset of  $A$ . Since  $A$  is a subspace of  $X$ , every open set  $U_k$  in  $A$  is of the form  $G \cap A$  for some open set  $G$  in  $X$ . Therefore, there exists open sets  $V(U_k)$  for each  $U_k$  such that  $A \cap V(U_k) = U_k$ .<sup>5</sup>

Define  $\mathcal{V} = \{X - A, V(U_1), V(U_2), \dots\}$ . Clearly,  $\mathcal{V}$  is a countable open cover<sup>6</sup> of  $X$ . We have  $X$  is countably compact, thus  $\mathcal{V}$  has a finite subcover, say  $\mathcal{V}'$ . Without loss of generality assume<sup>7</sup> that  $X - A \in \mathcal{V}'$ . Suppose  $X - A \notin \mathcal{V}'$ , then we can define another finite subcover  $\mathcal{V}' \cup \{X - A\}$ . Thus  $\mathcal{V}' = \{X - A, V(U_{n_1}), V(U_{n_2}), \dots, V(U_{n_k})\}$ .

Then the corresponding subcover  $\mathcal{U}' = \{U_{n_1}, U_{n_2}, \dots, U_{n_k}\}$  is a finite subcover of  $\mathcal{U}$ . Since countable open cover  $\mathcal{U}$  and closed subset  $A$  are arbitrary, every closed subset of  $X$  with relative topology is countably compact. Therefore, countable compactness is weakly hereditary.  $\square$

**Remark.** *Proof depends on the following,*

1. *There is an extension map,  $\psi : P(A) \rightarrow P(X)$  that preserve open sets (and closed sets). This  $\psi$  is an open map which not a true inverse of the restriction,  $r : P(X) \rightarrow P(A)$ , defined by  $r(G) = G \cap A$  for every subset  $G$  of  $X$ .*
2. *Also we rely on the subset  $A$  being closed. Suppose  $X$  have many countable open covers, but  $X$  has only uncountable open covers corresponding to a particular uncountable open cover of  $A$ . In such a case,  $X$  being countably compact is insufficient for  $A$  to be countably compact.*

### The behaviour of continuous functions

We will now study the nature of continuous functions defined on countably compact spaces. Suppose  $X, Y$  are topological space and function  $f : X \rightarrow Y$  is continuous. If  $X$  is countably compact, then  $f(X)$  is also countably compact.

<sup>4</sup>Suppose  $A$  is not a proper subset of  $X$ . Then  $X = A$  and  $A$  is countably compact.

<sup>5</sup>Relative topology,  $\mathcal{T}_{/A} = \{G \cap A : G \in \mathcal{T}\}$

<sup>6</sup> $X - A$  is open in  $X$ . If  $y \notin A$ , then  $y \in X - A$ . If  $y \in A$ , then  $y \in U_k$  for some  $k$ .

<sup>7</sup>Otherwise, you will have to consider two cases:  $X - A \in \mathcal{V}'$  and  $X - A \notin \mathcal{V}'$

Continuous images of countably compact spaces are countably compact. In other words, countable compactness is preserved under continuous functions.<sup>8</sup>

**Theorem 11.2.** *Countable compactness is preserved under continuous functions.[Joshi, 1983, 11.1.2]*

**Synopsis.** *Let  $X$  be countably compact and  $f : X \rightarrow Y$  be continuous. Suppose  $\mathcal{U}$  is a countable cover of  $f(X)$ , then  $X$  has a countable cover  $\mathcal{V}$  obtained by taking inverse images. Since  $X$  is countably compact,  $\mathcal{V}$  has a finite subcover  $\mathcal{V}'$ . Now taking images of members of  $\mathcal{V}'$ , we get a finite subcover  $\mathcal{U}'$  of  $f(X)$ .*

*Proof.* Suppose  $X$  is a countably compact space,  $Y$  is a topological space and  $f : X \rightarrow Y$  is a continuous function. Let  $\mathcal{U} = \{U_1, U_2, \dots\}$  be a countable cover of  $f(X)$  by set open in  $f(X)$ . We have to show that  $\mathcal{U}$  has a finite subcover.

Define  $\mathcal{V} = \{f^{-1}(U_1), f^{-1}(U_2), \dots\}$ . Then  $\mathcal{V}$  is a countable open cover of  $X$ , since  $f^{-1}(U_k)$  are open subsets of  $X$  and,

$$\begin{aligned} \bigcup_{k=1}^{\infty} U_k = f(X) &\implies f^{-1}\left(\bigcup_{k=1}^{\infty} U_k\right) = X \\ &\implies \bigcup_{k=1}^{\infty} f^{-1}(U_k) = X \end{aligned}$$

We have,  $\mathcal{V}$  is a countable open cover of  $X$ , which is a countably compact space. Therefore  $\mathcal{V}$  has a finite subcover  $\mathcal{V}' = \{f^{-1}(U_{n_1}), f^{-1}(U_{n_2}), \dots, f^{-1}(U_{n_k})\}$ .

$$\begin{aligned} \bigcup_{j=1}^k f^{-1}(U_{n_j}) = X &\implies f^{-1}\left(\bigcup_{j=1}^k U_{n_j}\right) = X \\ &\implies \bigcup_{j=1}^k U_{n_j} = f(X) \end{aligned}$$

Clearly  $\mathcal{U}' = \{U_{n_1}, U_{n_2}, \dots, U_{n_k}\}$  is a finite subcover of  $\mathcal{U}$ . Thus every countable open cover of  $f(X)$  by sets open in  $f(X)$  has a finite subcover. Therefore, continuous images of countably compact spaces are countably compact.  $\square$

**Remark.** 1. *For a continuous function,  $f : X \rightarrow Y$  the inverse images of open sets are open in  $X$ . The relation  $f^{-1} \subset f(X) \times X$  is not a function. However, we may consider a function,  $\psi : P(Y) \rightarrow P(X)$  such that  $\psi(U) = f^{-1}(U)$  for any subset  $U$  of  $Y$ . This  $\psi$  is an open map which maps open subsets of  $Y$  to open subsets of  $X$ .*

**Theorem 11.3.** *Every continuous, real-valued function on a countably compact, metric space is bounded and attains its extrema.[Joshi, 1983, 11.1.7]*

---

<sup>8</sup>A topological property is preserved under continuous functions if whenever a space has that property so does every continuous image of it.[Joshi, 1983, 6.1.9]

**Synopsis.** Let  $X$  be a countably compact space and function  $f : X \rightarrow \mathbb{R}$  be continuous. Then  $f(X) \subset \mathbb{R}$  is countably compact. Real line  $\mathbb{R}$  is metrisable<sup>9</sup>. Then  $f(X)$  is countably compact, metric space. Therefore  $f(X)$  compact.<sup>10</sup>. The subset  $f(X)$  of  $\mathbb{R}$  is bounded and closed, since every compact subset of  $\mathbb{R}$  is bounded and closed. Thus  $f(X)$  contains its supremum and infimum. Therefore,  $f$  is bounded and attains its extrema.

*Proof.* Let  $X$  be a countably compact space and  $f : X \rightarrow \mathbb{R}$  be continuous, real-valued function on the countably compact space,  $X$ . We have to show that  $f$  is bounded and attains its extrema.

Since countable compactness is preserved under continuous functions,  $f(X)$  is countably compact subset of  $\mathbb{R}$ . Since,  $f(X)$  is a subset of the metric space,  $\mathbb{R}$  and metrisability is hereditary,  $f(X)$  is again metrisable. (suppose) We have, every countably compact, metric space is compact. Then  $f(X)$  is a compact subset of  $\mathbb{R}$ .

Since every compact subset of  $\mathbb{R}$  is bounded and closed,  $f(X)$  is bounded and closed. Since every closed subset of  $\mathbb{R}$  contains supremum and infimum,  $f(X)$  contains its extrema. Therefore, every continuous, real-valued function on a countably compact space is bounded and attains its extrema.

We have assumed that every countably compact, metric space is compact. This result will be proved in the last section of this chapter.  $\square$

**Remark.** Since countably compact, metric spaces are compact. The above theorem can be used to prove that continuous, real-valued functions on a compact, metric space attains its extrema.

Due to the Lebesgue covering lemma, next result is quite simple.\*

**Theorem 11.4.** Every continuous, real-valued function on a countably compact, metric space is uniformly continuous.

**Proposition 11.5.** Let  $X$  be a first countable, Hausdorff space. Then every countably compact subset  $A$  of  $X$  is closed.[Joshi, 1983, Exercises 11.1.7]

### 11.1.2 Sequential Compactness

#### Weakly hereditary property

**Theorem 11.6.** Sequential compactness is weakly hereditary.[Joshi, 1983, Exercises 11.1.3]

#### The behaviour of continuous functions

**Theorem 11.7.** Sequential compactness is preserved under continuous functions.[Joshi, 1983, Exercises 11.1.4]

<sup>9</sup>[Joshi, 1983, 4.2 Example 4],  $\mathbb{R}$  with usual metric  $d : \mathbb{R} \rightarrow \mathbb{R}$ ,  $d(x, y) = |x - y|$

<sup>10</sup>[Joshi, 1983, 11.1.11] On metric spaces, countable compactness  $\implies$  compactness.

**Synopsis.** Let  $X$  be sequentially compact and function  $f : X \rightarrow Y$  be continuous. Then any sequence,  $\{y_k\}$  in  $f(X)$  has a sequence,  $\{x_k\}$  in  $X$  such that  $f(x_k) = y_k$ . Sequence  $\{x_k\}$  has a subsequence  $\{x_{n_k}\}$  converging to  $x$ , then sequence  $\{f(x_{n_k})\}$  in  $f(X)$  has the subsequence  $\{f(x_{n_k})\}$  converging to  $f(x)$ .

*Proof.* Let  $X$  be a sequentially compact space, function  $f : X \rightarrow Y$  be continuous and  $\{y_n\}$  be a sequence in  $f(X)$  subset of  $Y$ . Construct a sequence  $\{x_n\}$  such that  $f(x_k) = y_k, \forall k$ .

Every sequence in  $X$  has a convergent subsequence. Thus  $\{x_n\}$  has a subsequence  $\{x_{n_k}\}$  converging to  $x \in X$ . The image of this subsequence  $\{f(x_{n_k})\}$  is a subsequence of  $\{y_k\}$ . We claim that,  $\{f(x_{n_k})\}$  converges to  $f(x) \in f(X)$ .

Let  $U$  be an open set containing  $f(x)$ , then  $f^{-1}(U)$  is an open set containing  $x$ . Since  $\{x_{n_k}\}$  converges to  $x$ . There exists an integer  $n$  such that for every  $k \geq n, x_k \in f^{-1}(U)$ . Clearly, for each  $k \geq n, f(x_k) \in U$ . Since  $U$  is arbitrary,  $\{f(x_{n_k})\}$  converges to  $f(x)$ . Therefore, the image of any sequentially compact space is sequentially compact. In other words, sequentially compactness is preserved under continuous functions.  $\square$

**Remark.** 1. Given a sequence  $\{y_n\}$  in  $f(X)$ , there is a sequence of subsets  $\{U_n\}$  in  $P(Y)$  such that  $U_n = f^{-1}(y_n)$ . Since each  $U_n$  is non-empty, we can construct a sequence  $\{x_n\}$  in  $X$  using a choice function. The convergent subsequence of  $\{y_n\}$  depends on the selection of this choice function.

Given every sequentially compact, metric space is countably compact. We may assert the properties of countably compact, metric spaces on sequentially compact, metric spaces.

**Theorem 11.8.** Every continuous, real-valued function on a sequentially compact, metric space is bounded and attains its extrema.

**Theorem 11.9.** Every continuous, real-valued function on a sequentially compact, metric space is uniformly continuous. [Joshi, 1983, Exercises 11.1.6]

### 11.1.3 Countable Compactness on $T_1$ spaces

In this section, we are going to see four different characterisations of countable compactness in  $T_1$  spaces. The first two characterisations doesn't have anything to do with the  $T_1$  axiom.

**$T_1$  Space** A topological space  $X$  satisfy  $T_1$  axiom if for any two distinct points  $x, y \in X$ , there exists an open set  $U \subset X$  containing  $x$  but not  $y$ . [Joshi, 1983, 7.1.2]

**countable compactness** A topological space is countably compact if every countable open cover has a finite subcover. [Joshi, 1983, 11.1.1]

**finite intersection property** A family  $\mathcal{F}$  of subsets of  $X$  has finite intersection property (f.i.p.) if every finite subfamily of  $\mathcal{F}$  has a non-empty intersection. [Joshi, 1983, 10.2.6]

**accumulation point** A point  $x \in X$  is accumulation point of a subset  $A \subset X$  if every open set containing  $x$  has atleast one point of  $A$  other than  $x$ . [Joshi, 1983, 5.2.7]

**limit point** A point  $x \in X$  is a limit point of a sequence  $\langle x_k \rangle$  in  $X$  if for every open set  $U$  containing  $x$ , there exists an integer  $N \in \mathbb{N}$  such that  $x_k \in U$  for every  $k \geq N$ . [Joshi, 1983, 4.1.7]

**cluster point** A point  $x \in X$  is a cluster point of a sequence  $\langle x_k \rangle$  in  $X$  if for any neighbourhood  $V$  of  $x$ , the sequence  $\langle x_k \rangle$  assumes a point in  $V$  infinitely many times.<sup>11</sup>

### Countable compactness in $T_1$ spaces

**Theorem 11.10.** In a  $T_1$  space  $X$ , following statements are equivalent,

1.  $X$  is countably compact
2. Every countably family of closed subsets of  $X$  with finite intersection property have non-empty intersection.
3. Every infinite subset  $A \subset X$  has an accumulation point.<sup>12</sup>
4. Every sequence  $\langle x_k \rangle$  in  $X$  has a cluster point.
5. Every infinite open cover of  $X$  has a proper subcover. [Arens-Dugundji]

*Proof.* 1  $\implies$  2

Suppose  $X$  is countably compact. Let  $\mathcal{C} = \{C_1, C_2, \dots\}$  be a countable family of closed subsets of  $X$  with empty intersection. Define  $\mathcal{U} = \{X - C_1, X - C_2, \dots\}$  is a family of open subsets of  $X$ . By de Morgan's law,<sup>13</sup>

$$\bigcap_{k=1}^{\infty} C_k = \phi, \text{ then } X = X - \left( \bigcap_{k=1}^{\infty} C_k \right) = \bigcup_{k=1}^{\infty} (X - C_k)$$

We have  $\mathcal{U}$  is a countable cover of  $X$  and  $X$  is countably compact space. Thus  $\mathcal{U}$  has a finite subcover  $\mathcal{U}' = \{X - C_{n_1}, X - C_{n_2}, \dots, X - C_{n_k}\}$ .

$$\mathcal{U}' \text{ is a cover of } X, \text{ then } X = \bigcup_{j=1}^k (X - C_{n_j})$$

$$X - \bigcup_{j=1}^k (X - C_{n_j}) = \bigcap_{j=1}^k (X - (X - C_{n_j})) = \bigcap_{j=1}^k C_{n_j} = \phi$$

Now  $\mathcal{C}' = \{C_{n_1}, C_{n_2}, \dots, C_{n_k}\}$  has empty intersection. This is a contradiction to the finite intersection property of  $\mathcal{C}$ . Thus  $\mathcal{C}$  has non-empty intersection. Therefore, every countably family of closed subsets of  $X$  have non-empty intersection.

<sup>11</sup> $x$  is a cluster point of  $\langle x_k \rangle$  if for every integer  $N$ , there exists  $k > N$  such that  $x_k \in V$ . In other words,  $\langle x_k \rangle$  is frequently in  $V$ . [Joshi, 1983, 10.1.9]

<sup>12</sup>Every infinite subset of  $\mathbb{R}$  has a limit point is equivalent to the completeness axiom.

<sup>13</sup>Complement of Intersection = Union of complements,  $X - (C \cap D) = (X - C) \cup (X - D)$ ,

2  $\implies$  1

Let  $\mathcal{U} = \{U_1, U_2, \dots\}$  be a countable cover of  $X$ . Then  $\mathcal{C} = \{X - U_1, X - U_2, \dots\}$  is a countable family of closed subsets of  $X$ .

Let  $\mathcal{U}' = \{U_{n_1}, U_{n_2}, \dots, U_{n_k}\}$  be any finite subfamily of  $\mathcal{U}$ . Suppose  $X$  is not countably compact, then  $\mathcal{U}$  doesn't have a finite subcover. Therefore,  $\mathcal{U}'$  is not a cover of  $X$ . And  $\mathcal{C}$  is a family of closed sets with finite intersection property.

Therefore by assumption, the countable family of closed sets  $\mathcal{C}$  has a non-empty intersection.

$$\bigcap_{k=1}^{\infty} C_k \neq \phi, \text{ then } \bigcap_{k=1}^{\infty} C_k = \bigcap_{k=1}^{\infty} (X - U_k) = X - \left( \bigcup_{k=1}^{\infty} U_k \right) \neq \phi$$

Then  $\mathcal{U}$  is not a cover of  $X$  as well. This is a contradiction, therefore  $X$  is countably compact.

1  $\implies$  3

Suppose  $X$  is countably compact. Let  $A$  be an infinite subset of  $X$ . Suppose  $A$  doesn't have an accumulation point.

Let  $B$  be a countably infinite subset of  $A$ . Then  $B$  also doesn't have any accumulation point. Therefore, the derived set  $B'$  is empty. Thus  $B$  is a closed subset of  $X$ . Since countable compactness is weakly hereditary, subspace  $B$  is again countably compact.

For each point  $b \in B$ , there is an open set  $V_b$  such that  $V_b \cap B = \{b\}$ , since  $b \in B$  is not an accumulation point. Thus  $\mathcal{U} = \{V_b \cap B : b \in B\}$  is a countable open cover of  $B$ . Clearly,  $\mathcal{U}$  doesn't have any finite subcover.

This is a contradiction to  $B$  being countably compact. Therefore,  $A$  has an accumulation point.  $\square$

#### 11.1.4 Variations of Compactness on Metric Spaces

In this document, we will see that from metric space point of view these two notions were equivalent to the compactness and were used alternatively. For example : in functional analysis (semester 3), you will find definitions like 'a normed space is compact iff every sequence in it has a convergent subsequence', which is clearly sequential compactness for a topologist.

**Lindeloff** A topological space is Lindeloff iff every open cover has a countable subcover.

**First countable** A topological space is first countable iff every point in it has a countable local base.

**Second countable** A topological space is second countable iff it has a countable base.

**Base** A family of subsets  $\mathcal{B}$  of  $X$  is a base of a topological space if every open set can be expressed as union of some members of  $\mathcal{B}$

**Base Characterisation** A family of subsets  $\mathcal{B}$  of  $X$  is a base of a topological space iff for every  $x \in X$ , and for every neighbourhood  $U$  of  $x$ , there is a member  $B \in \mathcal{B}$  such that  $x \in B \subset U$ .

**Local Base** A family of subsets  $\mathcal{L}$  of  $X$  is a local base at point  $x \in X$  if for every neighbourhood  $U$  of  $x$ , there is a member  $L \in \mathcal{L}$  such that  $x \in L \subset U$ .

### Equivalence

We are going to see when these three notions: compactness, countable compactness and sequentially compactness are equivalent.

**Theorem 11.11.** *Countably compact, metric spaces are second countable.*

**Synopsis.** *For every positive real number  $r$ , there exists a non-empty maximal subsets  $A_r$  with every pair of points atleast  $r$  distance apart.  $A_r$  are finite. The union of maximal subsets  $A_{\frac{1}{n}}$  for each natural number  $n$  is a countable, dense subset  $D$  of  $X$ . Thus countably compact, metric spaces are separable. The family  $\mathcal{B}$  of all open balls with center at  $d \in D$  and rational radius is a countable, base for  $X$ . Thus countably compact, metric spaces are second countable.*

*Proof.* Let  $(X; d)$  be a countably compact,, metric space. For each positive real number  $r \in \mathbb{R}$ ,  $r > 0$  construct a family of subsets  $A_r \subset X$  such that it is a maximal set of points which are atleast  $r$  distances apart.

Then  $A_r$  is finite for every positive real number  $r$ . Suppose  $A_r$  is infinite for some real number  $r > 0$ , then  $A_r$  has a accumulation point, say  $x$  by the Characterisation of countable compactness of  $X$ .

Then every neighbourhood of  $x$  must intersect  $A_r$  at infinitely many points, since every metric space is a  $T_1$  space. Consider  $B(x, \frac{r}{2})$ . Since any two points of  $B(x, \frac{r}{2})$  are less than  $r$  distances apart, the intersection  $B(x, \frac{r}{2}) \cap A_r$  can have atmost one point in it. Thus for every positive real number  $r$ ,  $A_r$  is finite.

Define  $D = \cup_{n=1}^{\infty} A_{\frac{1}{n}}$ . We claim that  $D$  is a countable, dense subset of  $X$ .

Let  $x \in X$  and  $B(x, r)$  be an open ball containing  $x$ , then there exists integer  $n \in \mathbb{N}$  such that  $\frac{1}{n} < r$ .<sup>14</sup>

Then  $B(x, r) \cap D \neq \emptyset$ , since  $B(x, r) \cap A_{\frac{1}{n}} \neq \emptyset$ . Suppose  $B(x, r) \cap A_{\frac{1}{n}} = \emptyset$ , then  $A_{\frac{1}{n}}$  is not maximal. Since,  $x$  is atleast  $r > \frac{1}{n}$  distance apart from each points of  $A_{\frac{1}{n}}$ . Therefore,  $D$  intersects with every open set and thus dense in  $X$ .

We have have a countable, dense subset  $D$  of  $X$ . Therefore,  $X$  is separable. Now define  $\mathcal{B} = \{B(x, r) : r \in \mathbb{Q}, x \in D\}$ . Clearly,  $\mathcal{B}$  is a countable base for  $X$ . By the construction of  $\mathcal{B}$ ,  $X$  is second countable.<sup>15</sup>  $\square$

<sup>14</sup>By archimedean property of integers, we have  $\forall r \in \mathbb{R}, r > 0, \exists n \in \mathbb{N}$  such that  $nr > 1$ .

<sup>15</sup>Every separable, metric space is second countable.

**Countable Compactness, Lindeloff  $\iff$  Compactness**

**Theorem 11.12.** *A topological space  $X$  is compact iff it is countably compact, Lindeloff space.*

*Proof.* Let  $X$  be a compact space. Let  $\mathcal{U}$  be a countable open cover of  $X$ , then  $\mathcal{U}$  has a finite subcover  $\mathcal{U}'$ . Therefore, every compact space is countably compact.<sup>16</sup>

Conversely, suppose  $X$  is a countably compact, Lindeloff space. Since  $X$  is Lindeloff, every open cover  $\mathcal{U}$  has a countable subcover  $\mathcal{U}'$ . Since  $X$  countably compact, every countable open cover  $\mathcal{U}'$  has a finite subcover  $\mathcal{U}''$ . Thus every open cover  $\mathcal{U}$  has a finite subcover  $\mathcal{U}''$ . Therefore every countably compact, Lindeloff space is compact.  $\square$

**Countable Compactness, First Countable  $\implies$  Seq. Compactness**

**Theorem 11.13.** *Every countably compact, first countable space is Sequentially compact.*

*Proof.* Let  $X$  be a countably compact, first countable space. Let  $\{x_n\}$  be a sequence in  $X$ . By, equivalent conditions<sup>17</sup> of countably compact spaces, every sequence in countably compact space  $X$  has a cluster point, say  $x$ . We have,  $X$  is first countable. Therefore,  $X$  has a countable local base  $\mathcal{L}$  at  $x \in X$ . How to construct a subsequence of  $\{x_n\}$  converging to  $x$ ?<sup>18</sup>  $\square$

**Remark.** *Every sequentially compact space is countably compact.\**

**Theorem 11.14.** *In a second countable space, all the three forms of compactness are equivalent.[Joshi, 1983, 11.1.10]*

*Proof.* Every second countable space is both first countable and Lindeloff. Every countably compact, Lindeloff space is countably compact. Therefore every countably compact, second countable space compact. Again, every countably compact, first countable space is sequentially compact. Therefore every countably compact, second countable space is sequentially compact. Conversely, every compact space is countably compact and every sequentially compact space is countably compact.<sup>19</sup>  $\square$

**Theorem 11.15.** *In a metric space, all the three forms of compactness are equivalent.[Joshi, 1983, 11.1.11]*

*Proof.* In a metric space each form of compactness implies second countability. And in second countable spaces, they are all equivalent.  $\square$

<sup>16</sup>Countable compactness is a weaker notion than compactness.

<sup>17</sup>[Joshi, 1983, 11.1] Conditions 1,2, and 4 are equivalent.  $2 \implies 4$  without  $T_1$  axiom is out of scope.

<sup>18</sup>[Joshi, 1983, Exercises 10.1.11]

<sup>19</sup>Countable compactness is a weaker notion than sequential compactness as well.

# Interpolation & Curve Fitting

**Definitions 14.1.** Given  $(n + 1)$  data points  $(x_k, y_k)$ ,  $k = 0, 1, \dots, n$ , the problem of estimating  $y(x)$  using a function  $y : \mathbb{R} \rightarrow \mathbb{R}$  that satisfy the data points is the interpolation problem. ie,  $y(x_k) = y_k$ ,  $k = 0, 1, \dots, n$ .

**Definitions 14.2.** Given  $(n + 1)$  data points  $(x_k, y_k)$ ,  $k = 0, 1, \dots, n$ , the problem of estimating  $y(x)$  using a function  $y : \mathbb{R} \rightarrow \mathbb{R}$  that is sufficiently close to the data points is the curve-fitting problem.  
ie, Given  $\epsilon > 0$ ,  $|y(x_k) - y_k| < \epsilon$ ,  $k = 0, 1, \dots, n$ .

**Remark.** The data could be from scientific experiments or computations on mathematical models. The interpolation problem assumes that the data is accurate. But, curve-fitting problem assumes that there are some errors involved which are sufficiently small.

**Definitions 14.3.** Given  $(n + 1)$  data points  $(x_k, y_k)$ ,  $k = 0, 1, \dots, n$ , the problem of estimating  $y(x)$  using a polynomial function of degree  $n$  that satisfy the data points is the polynomial interpolation problem.

**Remark.** Polynomial is the simplest interpolant.[Kiusalaas, 2013, 3.2]

### 14.1 Polynomial Interpolation

There exists a unique polynomial of degree  $n$  that satisfy  $(n + 1)$  distinct data points. There are a few methods to find this polynomial : 1. Lagrange's method 2. Newton's method 3. Neville's method. The Neville's method is out of scope.

#### 14.1.1 Lagrange's Method

Interpolation polynomial<sup>1</sup> is given by,

$$P(x) = \sum_{i=0}^n y_i l_i(x), \text{ where } l_i(x) = \prod_{j=0, j \neq i}^n \frac{x - x_j}{x_i - x_j} \quad (14.1)$$

---

<sup>1</sup>Using  $P_n$  to represent some polynomial of degree  $n$ . It is quite a confusing a notation when it comes to Newton's method as author construct a psuedo-recursive definition.

**Remark.** Lagrange's cardinal functions  $l_i$ , are polynomials of degree  $n$  and

$$l_i(x_j) = \delta_{ij} = \begin{cases} 0, & i \neq j \\ 1, & i = j \end{cases}$$

**Proposition 14.4.** Error in polynomial interpolation is given by

$$f(x) - P(x) = \frac{(x - x_0)(x - x_1) \cdots (x - x_n)}{(n + 1)!} f^{(n+1)}(\xi) \quad (14.2)$$

where  $\xi \in (x_0, x_n)$

**Remark.** The error increases as  $x$  moves away from the unknown value  $\xi$ .

### 14.1.2 Newton's Method

The interpolation polynomial is given by,

$$P(x) = a_0 + a_1(x - x_0) + \cdots + a_n(x - x_0)(x - x_1) \cdots (x - x_{n-1}) \quad (14.3)$$

where  $a_i = \nabla^i y_i$ ,  $i = 0, 1, \dots, n$ .

**Remark.** For Newton's Method, it is assumed that  $x_0 < x_1 < \cdots < x_n$ .

**Remark.** Lagrange's method is conceptually simple. But, Newton's method is computationally more efficient than Lagrange's method.

#### Computing coefficients $a_i$ of the polynomial

The coefficients are given by,

$$a_0 = y_0, a_1 = \nabla y_1, a_2 = \nabla^2 y_2, a_3 = \nabla^3 y_3, \dots, a_n = \nabla^n y_n \quad (14.4)$$

**Remark.** The divided difference  $\nabla^i y_i$  are computed as follows:

$$\begin{aligned} \nabla y_1 &= \frac{y_1 - y_0}{x_1 - x_0} \\ \nabla y_2 &= \frac{y_2 - y_1}{x_2 - x_1} & \nabla^2 y_2 &= \frac{\nabla y_2 - \nabla y_1}{x_2 - x_1} \\ \nabla y_3 &= \frac{y_3 - y_2}{x_3 - x_2} & \nabla^2 y_3 &= \frac{\nabla y_3 - \nabla y_2}{x_3 - x_2} & \nabla^3 y_3 &= \frac{\nabla^2 y_3 - \nabla^2 y_2}{x_3 - x_2} \end{aligned}$$

$x_0$	$y_0$				
$x_1$	$y_1$	$\nabla y_1$			
$x_2$	$y_2$	$\nabla y_2$	$\nabla^2 y_2$		
$\dots$	$\dots$	$\dots$	$\dots$	$\ddots$	
$x_n$	$y_n$	$\nabla y_n$	$\nabla^2 y_n$	$\dots$	$\nabla^n y_n$

Table 14.1: The  $\nabla^i y_i$  Computation Table

**Remark.** *Practise Problems*

Find interpolation polynomial for the following data points :

1.  $\{(0, 7), (2, 11), (3, 28)\}$   
[Kiusalaas, 2013, Example 3.1]
2.  $\{(-2, -1), (1, 2), (4, 59), (-1, 4), (3, 24), (-4, -53)\}$   
[Kiusalaas, 2013, Example 3.2]
3.  $\{(-1.2, -5.76), (0.3, -5.61), (1.1, -3.69)\}$   
[Kiusalaas, 2013, Problem Set 3.1.1]
4.  $\{(-2, -1), (1, 2), (4, 59), (-1, 4), (3, 24), (-4, -53)\}$   
[Kiusalaas, 2013, Problem Set 3.1.6]
5.  $\{(-3, 0), (2, 5), (-1, -4), (3, 12), (1, 0)\}$   
[Kiusalaas, 2013, Problem Set 3.1.7]
6.  $\{(0, 1.225), (3, 0.905), (6, 0.652)\}$   
[Kiusalaas, 2013, Problem Set 3.1.9]

**Remark.** In Lagrange's Method, we can interpolate at the given point even without computing the polynomial. In Newton's method, we have to compute polynomial and then interpolate for the given point.

That is, evaluate the value of cardinal polynomials at the point and substitute in Equation 14.1 as shown in Section 3.2.[Kiusalaas, 2013, Example 3.1]

### 14.1.3 Implementation of Newton's Method

#### Program 14.5. Computing Coefficients

```
def coefficients(xData, yData):
    m = len(xData)
    a = yData.copy()
    for k in range(1, m):
        a[k:m] = (a[k:m] - a[k-1]) / (xData[k:m] - xData[k-1])
    return a
```

Line 1 : Defines a function which takes two arguments/parameters, named *xData* and *yData*. In [Kiusalaas, 2013, 3.2], you will find *coeffts* which I have changed to *coefficients*. *xData*, *yData* are numpy array objects. *xData* is a array with values  $x_0, x_1, \dots, x_n$ . And *yData* is array with values  $y_0, y_1, \dots, y_n$ . For example, the value of  $x_3$  can be accessed as *xData*[3].

Line 2 : The function *len()* is extended by numpy to give the length of array objects. In this context, *len(xData)* will return the value  $n+1$ , since there are  $n+1$  values in *xData* array.

Line 3 : We need a copy of *yData* to work with. Unlike other programming languages like java, in python *a = yData* will assign a new label *a* to the same memory location and manipulating *a* will corrupt the original data in *yData* as well. In order to avoid this, we are making a copy of the array object

using the array method provided by the numpy library.

*Line 4 : This is a python loop statement. This ask python interpreter to repeat the following sub-block  $m - 1$  times.<sup>2</sup> In this context, Line 5 will be executed  $n$  times, since the `range(1, m)` object is a list-type object with values  $1, 2, \dots, m - 1$ . And interpreter executes Line 5 for each values in the `range()` object, ie,  $k = 1, 2, \dots, m - 1$  before interpreting Line 6.*

*Line 5 : This is very nice feature available in python. This statement, evaluates  $m - k$  values in a single step, ie,  $a[k], a[k+1], \dots, a[m]$ . This calculation corresponds to subsequent columns of the divided difference table, that we are familiar with. For example, executing Line 5 with  $k = 3$  is same as evaluating the  $\nabla^3 y_j$  column. Note that the value  $a[0]$  is never updated and similarly  $a[2]$  changes when Line 5 is executed with  $k = 1, 2$ . From column 3 onward,  $a[2]$  is not updated. Therefore, after completing  $n$ th executing of the Line 5, we have  $a[0] = y_0$ ,  $a[1] = \nabla y_1$ ,  $a[2] = \nabla^2 y_2, \dots$ ,  $a[n] = \nabla^n y_n$ .*

*Line 6 : This returns the array  $a$  which is the array of coefficients.*

The logic of this program is in Line 4 and Line 5. So they need more explanation/understanding than anything else.

#### Program 14.6. Interpolating using Newton's Method

```
def interpolate(a, xData, x):
    n = len(xData)-1
    p = a[n]
    for k in range(1, n+1):
        p = a[n-k] + (x-xData[n-k])*p
    return p
```

The logic this program is in Line 3, Line 4 and Line 5.

*Line 3 : We initialize the polynomial with the coefficient  $a[n] = \nabla^n y_n = a_n$ .*

*Line 4 : We are going define the polynomial recursively. This takes exactly  $n$  steps further. So we use a loop which repeats  $n$  times.*

*Line 5 : The value of  $p$  and  $k$  changes each time Line 5 is executed. Let  $P_j$  be the value in  $p$  after executing Line 5 with  $k = j$ . Then,*

$$\begin{aligned} P_0 &= p = a[n] \\ P_1 &= a[n-1] + (x - x_{n-1})P_0 \\ P_2 &= a[n-2] + (x - x_{n-2})P_1 \\ &\vdots \\ P_n &= a[0] + (x - x_0)P_{n-1}. \end{aligned}$$

Clearly,  $P_n$  is the unique  $n$  degree polynomial given by the Newton's method.

#### Program 14.7. How to interpolate ?

<sup>2</sup>Python block is a group of statement with same level of indentation. A sub-block is a block with an additional indentation.

```

from numpy import array
xData = array([-2, 1, 4, -1, 3, -4]) #change as needed
yData = array([-1, 2, 59, 4, 24, -53]) #change as needed
a = coefficients(xData, yData)
print(interpolate(a, xData, 2))

```

You will have to define both the functions (*coefficients*, *interpolate*) before doing this.

Line 1 : For defining array objects, we need to import them from numpy library.

Line 2 : You can change this line according to the first component of the given data points.

Line 3 : You can change this line according to the second component of the given data points.

Line 4 : Call function *coefficients* and store the array returned into *a*

Line 5 : Call function *interpolate* to interpolate at  $x = 2$  and print the value  $P(2)$

**Program 14.8** (Just for Fun). We can do more using *sympy* !

```

from numpy import array
from sympy import Symbol
xData = array([-2, 1, 4, -1, 3, -4])
yData = array([-1, 2, 59, 4, 24, -53])
a = coefficients(xData, yData)
x = Symbol('x')
p = interpolate(a, xData, x)
p.subs({x:2})

```

**Remark.** *Programming Problems*

1.  $\{(0.15, 4.79867), (2.30, 4.49013), (3.15, 4.2243), (4, 85, 3.47313), (6.25, 2.66674), (7.95, 1.51909)\}$  [*Kiusalaas, 2013, Example 3.4*]
2.  $\{(0, -0.7854), (0.5, 0.6529), (1, 1.7390), (1.5, 2.2071), (2, 1.9425)\}$  [*Kiusalaas, 2013, Problem Set 3.1.5*]

#### 14.1.4 Limitations of Polynomial Interpolation

1. Inaccuracy - The error in interpolation increases as the point moves away from most of the data points.
2. Oscillation - As the number of data points considered for polynomial interpolation increases, the degree of the polynomial increases. And the graph of the interpolant tend to oscilate excessively. In such cases, the error in interpolation is quite high.

3. The best practice is to consider four to six data points nearest to the point of interest and ignore the rest of them.

**Remark.** *The interpolant obtained by joining cubic polynomials corresponding to four nearest data points each, is a cubic spline<sup>3</sup>.*

## 14.2 Roots of a Function

**Definitions 14.9.** *Let  $f : \mathbb{R} \rightarrow \mathbb{R}$ , then  $x \in \mathbb{R}$  is a root of  $f$  if  $f(x) = 0$ .*

**Remark.** *Suppose  $a < b$  and  $f(a), f(b)$  are nonzero and are of different signs. If  $f$  is continuous in  $[a, b]$ , then there is a point  $c \in [a, b]$  such that  $f(c) = 0$ .*

*Thus given  $a < b$  and  $f(a), f(b)$  are nonzero values of different sign, then there may be a bracketed root in  $[a, b]$ .*

*Note : There is no guarantee that there exists a root in  $[a, b]$  as we are not sure about the continuity of  $f$ .*

**Remark.** *Given a bracketed root, we can find it using*

1. *Bisection Method or*
2. *Newton-Raphson Method*

### 14.2.1 Bisection Method

Suppose  $a < b$  and  $f(a), f(b)$  are nonzero values of different signs. We evaluate  $f(c)$  where  $c = \frac{a+b}{2}$ . If  $f(c)$  is a nonzero value, then at least one of the pairs  $f(a), f(c)$  or  $f(c), f(b)$  are of different signs. WLOG suppose that  $f(a), f(c)$  are of different signs, then set  $b = c$  and  $c = \frac{a+b}{2}$ . And continue this process until we get sufficiently accurate value of a root.

**Remark.** *Suppose  $f(x) = x^5 - 2$ . Then  $f(0) = -2$ ,  $f(1) = -1$ ,  $f(2) = 30$ . Since  $f$  is known to be continuous, there is a bracketed root in  $[1, 2]$ . Now*

$$f(1.5) > 0 \implies [1, 1.5]$$

$$f(1.25) > 0 \implies [1, 1.25]$$

$$f(1.125) < 0 \implies [1.125, 1.25]$$

$$f(1.1875) > 0 \implies [1.125, 1.1875]$$

$$f(1.15375) > 0 \implies [1.125, 1.15375]$$

$$f(1.139375) < 0 \implies [1.139375, 1.15375]$$

$$f(1.1465625) < 0 \implies [1.1465625, 1.15375]$$

$$f(1.15015625) > 0 \implies [1.1465625, 1.15015625]$$

$$f(1.148359375) < 0 \implies [1.1483594, 1.15015625]$$

$$f(1.149257825) > 0 \implies [1.1483594, 1.14925783]$$

*Thus, we have 1.14 is a root of  $f$  with accuracy upto two decimal points.*

---

<sup>3</sup>Cubic spline is a function, the graph of which is piece-wise cubic

### 14.2.2 Newton-Raphson Method

Suppose  $f$  is differentiable at  $x \in \mathbb{R}$  and  $f(x) \neq 0$ . Then compute  $x = x - \frac{f(x)}{df(x)}$  and evaluate  $f(x)$ . Repeat this process to get more accurate value of a root near  $x$ .

**Remark.** Suppose  $f(x) = x^5 - 2$ . Then  $df(x) = 5x^4$ . Let  $x = 2$ . Then

$$x = 2 - \frac{30}{80} \implies f(1.625) = 9.330$$

$$x = 1.625 - \frac{9.330}{34.86} \implies f(1.35735) = 2.6074$$

$$x = 1.35735 - \frac{2.6074}{16.9721} \implies f(1.20373) = 0.52733$$

$$x = 1.20373 - \frac{0.52733}{10.4975} \implies f(1.15351) = 0.04224$$

$$x = 1.15351 - \frac{0.04224}{8.85225} \implies f(1.148738) = 0.00034312$$

Thus we have 1.1487 is quite close to a root of  $f$ .

## Chapter 16

# Fourier Series and Fourier Integrals

### 16.1 The Weierstrass Approximation Theorem

Every continuous, real valued function on a compact interval has a polynomial approximation.[apo, 1973, Theorem 11.17]

**Theorem 16.1** (Weierstrass). *Let  $f$  be a real-valued, continuous function on a compact interval  $[a, b]$ . Then for every  $\epsilon > 0$ , there is a polynomial  $p$  such that  $|f(x) - p(x)| < \epsilon$  for every  $x \in [a, b]$ .*

**Synopsis.** *Given a real-valued continuous function on compact interval  $[a, b]$ , we can construct a real-valued, continuous function  $g$  on  $\mathbb{R}$  which is periodic with period  $2\pi$ . We have, if  $f \in L(I)$  and  $f$  is bounded almost everywhere in  $I$ , then  $f \in L^2(I)$ . [apo, 1973, Theorem 10.52]. By Fejer's theorem ([apo, 1973, Theorem 11.15]), the fourier series generated by  $g$  ([apo, 1973, definition 11.3]) converges to the Cesaro sum ([apo, 1973, Definition 8.47]), which is  $g$  itself in this case. Thus for any  $\epsilon > 0$ , there is a finite sum of trigonometric functions. The power series expansions of trigonometric functions ([apo, 1973, definition 9.27]) being uniformly convergent, there exists a polynomial  $p_m$  which approximates  $g$ . And we can construct  $p$  (polynomial approximation of  $g$ ) using  $p_m$ .*

*Proof.* Define  $g : \mathbb{R} \rightarrow \mathbb{R}$ ,

$$g(t) = \begin{cases} f(a + (b-a)t/\pi), & t \in [0, \pi) \\ f(a + (2\pi - t)(b-a)/\pi), & t \in [\pi, 2\pi] \\ g(t - 2n\pi), & t > 2\pi, n \in \mathbb{N} \\ g(t + 2n\pi), & t < 0, n \in \mathbb{N} \end{cases}$$

Thus  $g$  is a continuous, real-valued, periodic function with period  $2\pi$  such that

$$f(x) = g\left(\frac{\pi(x-a)}{b-a}\right), \quad x \in [a, b] \quad (16.1)$$

The fourier series generated by  $g$  is given by,

$$g(t) \sim \frac{a_0}{2} + \sum_{k=1}^{\infty} (a_k \cos kt + b_k \sin kt)$$

$$\text{where } a_k = \frac{1}{\pi} \int_0^{2\pi} f(t) \cos kt \, dt, \quad b_k = \frac{1}{\pi} \int_0^{2\pi} f(t) \sin kt \, dt$$

Let  $\{s_n(t)\}$  be the sequence of partial sums of the fourier series generated by  $g$ . And  $\{\sigma_n(t)\}$  be the sequence of averages of  $s_n(t)$  given by,

$$\sigma_n(t) = \frac{1}{n} \sum_{k=1}^n s_k(t), \text{ where } s_k(t) = \frac{a_0}{2} + \sum_{j=1}^k (a_j \cos jt + b_j \sin jt)$$

Function  $f \in L(I)$  being real-valued continuous function on a compact interval, it is bounded and hence is Lebesgue square integrable, ie,  $f \in L^2(I)$ . Thus,  $g \in L^2(I)$ .

Since  $g$  is continous on  $\mathbb{R}$ , the function  $s : \mathbb{R} \rightarrow \mathbb{R}$  defined by,

$$s(t) = \lim_{h \rightarrow 0^+} \frac{g(t+h) - g(t-h)}{2}$$

is well-defined on  $\mathbb{R}$  and  $s(t) = g(t)$ ,  $\forall t \in \mathbb{R}$ .

Then by Fejer's Theorem, the sequence  $\{\sigma_n(t)\}$  converges uniformly to  $g(t)$  for every  $t \in \mathbb{R}$ . Thus, given  $\epsilon > 0$ , there exists  $N \in \mathbb{N}$  such that  $\forall t \in \mathbb{R}$ ,  $|g(t) - \sigma_N(t)| < \frac{\epsilon}{2}$ .

We have,

$$\sigma_N(t) = \sum_{k=0}^N (A_k \cos kt + B_k \sin kt), \text{ where } A_k, B_k \in \mathbb{R} \quad (16.2)$$

By the power series expansion of the trigonometric functions about origin,

$$\cos kt = \sum_{j=1}^{\infty} \left( \frac{\cos^{(j)} 0}{j!} (kt)^j \right) = \sum_{j=1}^{\infty} A'_j t^j \text{ where } A'_j \in \mathbb{R} \quad (16.3)$$

$$\sin kt = \sum_{j=1}^{\infty} \left( \frac{\sin^{(j)} 0}{j!} (kt)^j \right) = \sum_{j=1}^{\infty} B'_j t^j \text{ where } B'_j \in \mathbb{R} \quad (16.4)$$

Since the above power series expansions of trigonometric functions are uniformly convergent, their finite linear combination  $\{\sigma_N(t)\}$  is also uniformly convergent. ie, Given  $\epsilon > 0$  there exists  $m \in \mathbb{N}$  such that for every  $t \in \mathbb{R}$

$$\left| \sum_{k=0}^m C_k t^k - \sigma_N(t) \right| < \frac{\epsilon}{2} \text{ where } C_k \in \mathbb{R}$$

Therefore,  $|p_m(t) - g(t)| \leq |p_m(t) - \sigma_N(t)| + |\sigma_N(t) - g(t)| < \epsilon$  where  $p_m(t) = \sum_{k=0}^m C_k t^k$ . Define  $p : [a, b] \rightarrow \mathbb{R}$  by,

$$p(x) = p_m \left( \frac{\pi(x-a)}{b-a} \right) \quad (16.5)$$

By equations 16.1 and 16.5,  $|p(x) - f(x)| < \epsilon$  for every  $x \in [a, b]$ .  $\square$

## 16.2 Other Forms of Fourier Series

Let  $f \in L([0, 2\pi])$ , then the fourier series generated by  $f$  is given by,

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$$

$$\text{where } a_n = \frac{1}{\pi} \int_0^{2\pi} f(t) \cos nt \, dt, \quad b_n = \frac{1}{\pi} \int_0^{2\pi} f(t) \sin nt \, dt$$

By Euler's formula  $e^{inx} = \cos nx + i \sin nx$ . We have,  $\cos nx = \frac{(e^{inx} + e^{-inx})}{2}$  and  $\sin nx = \frac{(e^{inx} - e^{-inx})}{2i}$

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{\infty} (\alpha_n e^{inx} + \beta_n e^{-inx})$$

$$\text{where } \alpha_n = \frac{(a_n - ib_n)}{2} \quad \beta_n = \frac{(a_n + ib_n)}{2}$$

Therefore, by assigning  $\alpha_0 = a_0/2$ ,  $\alpha_{-n} = \beta_n$ , we get the following exponential form of fourier series generated by  $f$ ,

$$f(x) \sim \sum_{n=-\infty}^{\infty} \alpha_n e^{inx} \text{ where } \alpha_n = \frac{1}{2\pi} \int_0^{2\pi} f(t) e^{-int} \, dt$$

Note : If  $f$  is periodic with period  $2\pi$ , then the interval of integration  $[0, 2\pi]$  can be replaced with any interval of length  $2\pi$ . eg.  $[-\pi, \pi]$

### 16.2.1 Periodic with period $p$

Let  $f \in L([0, p])$  and  $f$  is periodic with period  $p$ . Then

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{\infty} \left( a_n \cos \frac{2\pi nx}{p} + b_n \sin \frac{2\pi nx}{p} \right)$$

$$\text{where } a_n = \frac{2}{p} \int_0^p f(t) \cos \frac{2\pi nt}{p} \, dt \quad b_n = \frac{2}{p} \int_0^p f(t) \sin \frac{2\pi nt}{p} \, dt$$

Therefore, we have the exponential form of the above fourier series given by,

$$f(x) \sim \sum_{n=-\infty}^{\infty} \alpha_n e^{\frac{2\pi i n x}{p}}, \text{ where } \alpha_n = \frac{1}{p} \int_0^p f(t) e^{\frac{-2\pi i n t}{p}} \, dt$$

## 16.3 Fourier Integral Theorem

**Theorem 16.2** (Fourier Integral Theorem). *Let  $f \in L(-\infty, \infty)$ . Suppose  $x \in \mathbb{R}$  and an interval  $[x - \delta, x + \delta]$  about  $x$  such that either*

1.  *$f$  is of bounded variation on an interval  $[x - \delta, x + \delta]$  about  $x$  or*

2. both limits  $f(x+)$  and  $f(x-)$  exists and both Lebesgue integrals

$$\int_0^\delta \frac{f(x+t) - f(x+)}{t} dt \text{ and } \int_0^\delta \frac{f(x-t) - f(x-)}{t} dt$$

exists.

Then,

$$\frac{f(x+) + f(x-)}{2} = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^\infty f(u) \cos v(u-x) du dv,$$

the integral  $\int_0^\infty$  being an improper Riemann integral.

**Synopsis.**

$$f(x+t) \frac{\sin \alpha t}{\pi t} dt \rightarrow f(u) \frac{\sin \alpha(u-x)}{\pi(u-x)} \rightarrow \frac{f(u)}{\pi} \int_0^\alpha \cos v(u-x) dv$$

By Riemann-Lebesgue lemma[apo, 1973, Theorem 11.6],

$$f \in L(I) \implies \lim_{\alpha \rightarrow +\infty} \int_I f(x) \sin \alpha t dt = 0$$

By Jordan's Theorem[apo, 1973, Theorem 10.8], if  $g$  is of bounded variation on  $[0, \delta]$ , then

$$\lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta g(t) \frac{\sin \alpha t}{t} dt = g(0+)$$

By Dini's Theorem[apo, 1973, Theorem 10.9], if the limit  $g(x+)$  exists and Lebesgue integral  $\int_0^\delta \frac{g(t)+g(0+)}{t} dt$  exists for some  $\delta > 0$ , then

$$\lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta g(t) \frac{\sin \alpha t}{t} dt = g(0+)$$

The order of Lebesgue integrals can be interchanged[apo, 1973, Theorem 10.40],

Suppose  $f \in L(X)$  and  $g \in L(Y)$ . Then

$$\int_X f(x) \left( \int_Y g(y) k(x, y) dy \right) dx = \int_Y g(y) \left( \int_X f(x) k(x, y) dx \right) dy$$

*Proof.* Consider  $\int_{-\infty}^\infty f(x+t) \frac{\sin \alpha t}{\pi t} dt$ . We prove that this integral is equal to the either sides.

$$\int_{-\infty}^\infty f(x+t) \frac{\sin \alpha t}{\pi t} dt = \int_{-\infty}^{-\delta} + \int_{-\delta}^0 + \int_0^{-\delta} + \int_\delta^\infty f(x+t) \frac{\sin \alpha t}{\pi t} dt$$

We have, function  $\frac{f(x+t)}{\pi t}$  is bounded on  $(-\infty, -\delta) \cup (\delta, \infty)$ , hence  $\frac{f(x+t)}{\pi t}$  is Lebesgue integrable on  $(-\infty, -\delta) \cup (\delta, \infty)$ .

By Riemann Lebesgue lemma,

$$\frac{f(x+t)}{\pi t} \in L(-\infty, -\delta) \implies \int_{-\infty}^{-\delta} f(x+t) \frac{\sin \alpha t}{\pi t} dt = 0,$$

$$\frac{f(x+t)}{\pi t} \in L(\delta, \infty) \implies \int_\delta^\infty f(x+t) \frac{\sin \alpha t}{\pi t} dt = 0$$

**Case 1** Suppose  $f$  is of bounded variation on  $[x - \delta, x + \delta]$ , put  $g(t) = f(x + t)$  then  $g$  is of bounded variation on  $[-\delta, \delta]$ . Thus  $g$  is of bounded variation on  $[0, \delta]$ . Then by Jordan's Theorem

$$\lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta f(x + t) \frac{\sin \alpha t}{t} dt = \lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta g(t) \frac{\sin \alpha t}{t} dt = g(0+) = f(x+)$$

**Case 2** Suppose both the limits  $f(x+)$  and  $f(x-)$  exists and both Lebesgue integrals

$$\int_0^\delta \frac{f(x + t) - f(x+)}{t} dt \text{ and } \int_0^\delta \frac{f(x - t) - f(x-)}{t} dt$$

exists.

Thus, we have  $f(x+)$  exists and the Lebesgue integral  $\int_0^\delta \frac{f(x+t)-f(x+)}{t} dt$  exists. Put  $g(t) = f(x + t)$ , then  $g(0+) = f(x+)$  exists and the Lebesgue integral  $\int_0^\delta \frac{g(t)-g(0+)}{t} dt$  exists, then by Dini's Theorem,

$$\lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta f(x + t) \frac{\sin \alpha t}{t} dt = \lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta g(t) \frac{\sin \alpha t}{t} dt = g(0+) = f(x+)$$

Similarly,  $f(x-)$  exists and the Lebesgue integral  $\int_0^\delta \frac{f(x-t)-f(x-)}{t} dt$  exists. Put  $g(t) = f(x - t)$ , then  $g(0+) = f(x-)$  exists and the Lebesgue integral  $\int_0^\delta \frac{g(t)-g(0+)}{t} dt$  exists, then by Dini's Theorem,

$$\begin{aligned} \lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_{-\delta}^0 f(x + t) \frac{\sin \alpha t}{t} dt &= \lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta f(x - \tau) \frac{\sin \alpha \tau}{\tau} d\tau \\ &= \lim_{\alpha \rightarrow +\infty} \frac{2}{\pi} \int_0^\delta g(\tau) \frac{\sin \alpha \tau}{\tau} d\tau = g(0+) = f(x-) \end{aligned}$$

Then by either cases,

$$\begin{aligned} \lim_{\alpha \rightarrow +\infty} \int_{-\infty}^\infty f(x + t) \frac{\sin \alpha t}{\pi t} dt &= \lim_{\alpha \rightarrow +\infty} \int_{-\delta}^0 + \int_0^\delta f(x + t) \frac{\sin \alpha t}{\pi t} dt \\ &= \frac{f(x+) + f(x-)}{2} \end{aligned}$$

We have,  $\int_0^\alpha \cos v(u - x) dv = \frac{\sin v(u-x)}{u-x}$ .

$$\begin{aligned} \lim_{\alpha \rightarrow +\infty} \int_{-\infty}^\infty f(x) \frac{\sin \alpha t}{\pi t} dt &= \lim_{\alpha \rightarrow +\infty} \int_{-\infty}^\infty f(u) \frac{\sin \alpha(u-x)}{u-x} du, \text{ (put } u = x + t) \\ &= \lim_{\alpha \rightarrow +\infty} \int_{-\infty}^\infty f(u) \left( \int_0^\alpha \cos v(u-x) dv \right) du \\ &= \lim_{\alpha \rightarrow +\infty} \int_0^\alpha \left( \int_{-\infty}^\infty f(u) \cos v(u-x) du \right) dv, \end{aligned}$$

since, the order of Lebesgue integrals can be reversed.

$$= \int_0^\infty \left( \int_{-\infty}^\infty f(u) \cos v(u-x) du \right) dv$$

where,  $\int_0^\infty$  is not a Lebesgue integral, but an improper Riemann integral

Therefore,

$$\begin{aligned} \int_0^\infty \left( \int_{-\infty}^\infty f(u) \cos v(u-x) du \right) dv &= \lim_{\alpha \rightarrow +\infty} \int_{-\infty}^\infty f(x) \frac{\sin \alpha t}{\pi t} dt \\ &= \frac{f(x+) + f(x-)}{2} \end{aligned}$$

□

**Remark.** If a function  $f$  on  $(-\infty, \infty)$  is non-periodic, then it may not have a fourier series representation. In such cases, we have fourier integral representation.

## 16.4 Exponential form of Fourier Integral Theorem

Let  $f \in L(-\infty, \infty)$ . Suppose  $x \in \mathbb{R}$  and an interval  $[x - \delta, x + \delta]$  about  $x$  such that either

1.  $f$  is of bounded variation on an interval  $[x - \delta, x + \delta]$  about  $x$  or
2. both limits  $f(x+)$  and  $f(x-)$  exists and both Lebesgue integrals

$$\int_0^\delta \frac{f(x+t) - f(x+)}{t} dt \text{ and } \int_0^\delta \frac{f(x-t) - f(x-)}{t} dt$$

exists.

Then,

$$\frac{f(x+) + f(x-)}{2} = \lim_{\alpha \rightarrow \infty} \frac{1}{2\pi} \int_{-\alpha}^\alpha \left( \int_{-\infty}^\infty f(u) e^{iv(u-x)} du \right) dv$$

*Proof.* Let  $F(v) = \int_{-\infty}^\infty f(u) \cos v(u-x) du$ . Then  $F(v) = F(-v)$  and

$$\begin{aligned} \lim_{\alpha \rightarrow \infty} \frac{1}{2\pi} \int_{-\alpha}^\alpha F(v) dv &= \lim_{\alpha \rightarrow \infty} \frac{1}{\pi} \int_0^\alpha \int_{-\infty}^\infty f(u) \cos v(u-x) du dv \\ &= \frac{f(x+) + f(x-)}{2} \end{aligned}$$

Let  $G(v) = \int_{-\infty}^\infty f(u) \sin v(u-x) du$ . Then  $G(v) = -G(-v)$  and

$$\lim_{\alpha \rightarrow \infty} \frac{1}{2\pi} \int_{-\alpha}^\alpha G(v) dv = 0$$

Thus

$$\lim_{\alpha \rightarrow \infty} \frac{1}{2\pi} \int_{-\alpha}^\alpha F(v) + iG(v) dv = \frac{f(x+) + f(x-)}{2}$$

□

## 16.5 Integral Transforms

**Definitions 16.3.** Integral transform  $g(y)$  of  $f(x)$  is a Lebesgue integral or Improper Riemann integral of the form

$$g(y) = \int_{-\infty}^{\infty} K(x, y) f(x) dx$$

, where  $K$  is the kernel of the transform. We write  $g = \mathcal{K}(f)$ .

**Remark.** Integral transforms(operators) are linear operators. ie,  $\mathcal{K}(af_1 + bf_2) = a\mathcal{K}f_1 + b\mathcal{K}f_2$

**Remark.** A few commonly used integral transforms,

1. Exponential Fourier Transform  $\mathcal{F}$ ,

$$\mathcal{F}f = \int_{-\infty}^{\infty} e^{-ixy} f(x) dx$$

2. Fourier Cosine Transform  $\mathcal{C}$ ,

$$\mathcal{C}f = \int_0^{\infty} \cos xy f(x) dx$$

3. Fourier Sine Transform  $\mathcal{S}$ ,

$$\mathcal{S}f = \int_0^{\infty} \sin xy f(x) dx$$

4. Laplace Transform  $\mathcal{L}$ ,

$$\mathcal{L}f = \int_0^{\infty} e^{-xy} f(x) dx$$

5. Mellin Transform  $\mathcal{M}$ ,

$$\mathcal{M}f = \int_0^{\infty} x^{y-1} f(x) dx$$

**Remark.** Suppose  $f(x) = 0, \forall x < 0$ .

$$\int_{-\infty}^{\infty} e^{-ixy} f(x) dx = \int_0^{\infty} e^{-ixy} f(x) dx = \int_0^{\infty} \cos xy f(x) dx + i \int_0^{\infty} \sin xy f(x) dx$$

$$\mathcal{F}f = \mathcal{C}f + i\mathcal{S}f$$

Therefore Fourier Cosine  $\mathcal{C}$  and Sine  $\mathcal{S}$  transforms are special cases of fourier integral transform,  $\mathcal{F}$  provided  $f$  vanishes on negative real axis.

**Remark.** Let  $y = u + iv$ ,  $f(x) = 0$ ,  $\forall x < 0$ .

$$\int_0^\infty e^{-xy} f(x) dx = \int_0^\infty e^{-xu} e^{-ixv} f(x) dx = \int_0^\infty e^{-ixv} \phi_u(x) dx$$

where  $\phi_u(x) = e^{-xu} f(x)$ .

$$\mathcal{L}f = \mathcal{F}\phi_u$$

Therefore Laplace transform,  $\mathcal{L}$  is a special case of Fourier integral transform,  $\mathcal{F}$ .

**Remark.** Let  $g(y) = \mathcal{F}f(x)$ .

$$g(y) = \int_{-\infty}^\infty e^{-ixy} f(x) dx$$

Suppose  $f$  is continuous at  $x$ , then by fourier integral theorem,

$$\begin{aligned} f(x) &= \frac{1}{2\pi} \int_{-\infty}^\infty \left( \int_{-\infty}^\infty f(u) e^{iv(u-x)} du \right) dv \\ &= \int_{-\infty}^\infty e^{-ivx} \left( \frac{1}{2\pi} \int_{-\infty}^\infty e^{ivu} f(u) du \right) dv \\ &= \int_{-\infty}^\infty g(v) e^{-ivx} dv = \mathcal{F}g \text{ where } g(v) = \frac{1}{2\pi} \int_{-\infty}^\infty f(u) e^{ivu} du \end{aligned}$$

The above function  $g(v)$  gives the **inverse fourier transformation** of  $f$ .

Let  $g$  be fourier transform of  $f$ , then  $f$  is uniquely determined by its fourier transform  $g$  by,

$$f(x) = \mathcal{F}^{-1}g(y) = \frac{1}{2\pi} \lim_{\alpha \rightarrow \infty} \int_{-\alpha}^\alpha g(y) e^{ixy} dy$$

6. Inverse Fourier Transform  $\mathcal{F}^{-1}$ ,

$$\mathcal{F}^{-1}f = \int_{-\infty}^\infty \frac{e^{ixy}}{2\pi} f(x) dx$$

## 16.6 Convolutions

**Definitions 16.4.** Let  $f, g \in L(-\infty, \infty)$ . Let  $S$  be the set of all points  $x$  for which the Lebesgue integral

$$h(x) = \int_{-\infty}^\infty f(t)g(x-t)dt$$

exists. Then the function  $h : S \rightarrow \mathbb{R}$  is a convolution of  $f$  and  $g$ . And  $h = f * g$ .

**Remark.** Convolution operator is commutative.

ie,  $h = f * g = g * f$

**Remark.** Suppose  $f, g$  vanishes on negative real axis, then

$$h(x) = \int_{-\infty}^\infty f(t) g(x-t) dt = \int_{-\infty}^0 + \int_0^x + \int_x^\infty f(t) g(x-t) dt = \int_0^x f(t) g(x-t) dt$$

**Remark.** Singularity is a point at which the convolution integral fails to exist.

**Theorem 16.5.** Let  $f, g \in L(\mathbb{R})$  and either  $f$  or  $g$  is bounded in  $\mathbb{R}$ . Then the convolution integral

$$h(x) = \int_{-\infty}^{\infty} f(t)g(x-t)dt$$

exists for every  $x \in \mathbb{R}$  and the function  $h$  so defined is bounded in  $\mathbb{R}$ . In addition, if the bounded function is continuous on  $\mathbb{R}$ , then  $h$  is continuous and  $h \in L(\mathbb{R})$ .

**Synopsis.**

*Proof.*

□

**Remark.** If  $f, g$  are both unbounded, the convolution integral may not exist.

$$\text{eg: } f(t) = \frac{1}{\sqrt{t}}, \quad g(t) = \frac{1}{\sqrt{1-t}}$$

**Theorem 16.6.** Let  $f, g \in L^2(\mathbb{R})$ . Then the convolution integral  $f * g$  exists for each  $x \in \mathbb{R}$  and the function  $h : \mathbb{R} \rightarrow \mathbb{R}$  defined by  $h(x) = f * g(x)$  is bounded in  $\mathbb{R}$ .

**Synopsis.**

*Proof.*

□

## 16.7 The Convolution Theorem for Fourier Transforms

**Theorem 16.7.** Let  $f, g \in L(\mathbb{R})$  and either  $f$  or  $g$  is continuous and bounded on  $\mathbb{R}$ . Let  $h = f * g$ . Then for every real  $u$ ,

$$\int_{-\infty}^{\infty} h(x)e^{-ixu}dx = \left( \int_{-\infty}^{\infty} f(t)e^{-itu}dt \right) \left( \int_{-\infty}^{\infty} g(y)e^{-iyu}dy \right)$$

The integral on the left exists both as a Lebesgue integral and an improper Riemann integral.

**Synopsis.**

*Proof.*

□

**Remark** (Application of Convolution Theorem).

$$B(p, q) = \frac{\Gamma p \Gamma q}{\Gamma p + q}, \text{ where } B(p, q) = \int_0^1 x^{p-1}(1-x)^{q-1}dx, \quad \Gamma p = \int_0^{\infty} t^{p-1}e^{-t}dt$$

## Chapter 17

# Multivariate Differential Calculus

In this chapter, we deal with real functions of several variables. Instead of  $\mathbf{c}$ , we write  $\bar{c} \in \mathbb{R}^n$ , then  $\bar{c} = (c_1, c_2, \dots, c_n)$  where  $c_j \in \mathbb{R}$  for every  $j = 1, 2, \dots, n$ . Again, suppose  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  and  $f(\bar{x}) = \bar{y}$ , then  $\bar{y} = (y_1, y_2, \dots, y_m)$  where each  $y_k$  is real. The unit co-ordinate vector,  $\bar{u}_k$  is given by  $u_{kj} = \delta_{j,k}$

### 17.1 Directional Derivative

*Motivation :* The existence of all partial derivatives of a multivariate real function  $f$  at a point  $\bar{c}$  doesn't imply the continuity of  $f$  at  $\bar{c}$ . Thus, we need a suitable generalisation for the partial derivative which could characterise continuity. And directional derivative is such an attempt.

**Definitions 17.1** (Directional Derivative). *Let  $S \subset \mathbb{R}^n$  and  $f : S \rightarrow \mathbb{R}^m$ . Let  $\bar{c}$  be an interior points of  $S$  and  $\bar{u} \in \mathbb{R}^n$ , then there exists an open ball  $B(\bar{c}, r)$  in  $S$ . Also for some  $\delta > 0$  the line segment  $\alpha : [0, \delta] \rightarrow S$  given by  $\alpha(t) = \bar{c} + t\bar{u}$  lie in  $B(\bar{c}, r)$ .*

*Then the Directional derivative of  $f$  at an interior point  $\bar{c}$  in the direction  $\bar{u}$  is given by*

$$f'(\bar{c}, \bar{u}) = \lim_{h \rightarrow 0} \frac{f(\bar{c} + h\bar{u}) - f(\bar{c})}{h}$$

**Remark.** *The direction derivative of  $f$  at an interior point  $\bar{c}$  in the direction  $\bar{u}$  exists only if the above limit exists.*

**Remark.** *Example, [apo, 1973, Exercise 12.2a]*

*Suppose  $\bar{x}, \bar{a}, \bar{c}, \bar{u} \in \mathbb{R}^n$ . Let  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  such that  $f(\bar{x}) = \bar{a} \cdot \bar{x}$ . Then*

$$f'(\bar{c}, \bar{u}) = \lim_{h \rightarrow 0} \frac{\bar{a} \cdot (\bar{c} + h\bar{u}) - \bar{a} \cdot \bar{c}}{h} = \bar{a} \cdot \bar{u}$$

**Remark** (Properties). *Let  $f : S \rightarrow \mathbb{R}^m$ , where  $S \subset \mathbb{R}^n$*

1.  $f'(\bar{c}, \bar{0}) = \bar{0}$

*Note : The zero vectors belongs to  $\mathbb{R}^n, \mathbb{R}^m$  respectively.*

2.  $f'(\bar{c}, \bar{u}_k) = \frac{\partial f}{\partial u_k}(\bar{c}) = D_k f(\bar{c})$ , the  $k^{th}$  partial derivative of  $f$ .
3. Let  $f = (f_1, f_2, \dots, f_m)$ , such that  $f(\bar{c}) = (f_1(\bar{c}), f_2(\bar{c}), \dots, f_m(\bar{c}))$ . Then,
 
$$\exists f'(\bar{c}, \bar{u}) \iff \forall k, \exists f'_k(\bar{c}, \bar{u}) \text{ and } f'(\bar{c}, \bar{u}) = (f'_1(\bar{c}, \bar{u}), f'_2(\bar{c}, \bar{u}), \dots, f'_m(\bar{c}, \bar{u}))$$
 ie, Directional derivative of  $f$  exists iff directional derivative of each component function  $f_k$  exists. And the components of the directional derivatives of  $f$  are the directional derivatives of the components of  $f$ .  
 Thus  $D_k f(\bar{c}) = (D_k f_1(\bar{c}), D_k f_2(\bar{c}), \dots, D_k f_m(\bar{c}))$  holds.
4. Let  $F(t) = f(\bar{c} + t\bar{u})$ , then  $F'(0) = f'(\bar{c}, \bar{u})$  and  $F'(t) = f'(\bar{c} + t\bar{u}, \bar{u})$
5. Let  $f(\bar{c}) = \bar{c} \cdot \bar{c} = \|\bar{c}\|^2$ , and  $F(t) = f(\bar{c} + t\bar{u})$ , then  $F'(t) = 2\bar{c} \cdot \bar{u} + 2t\|\bar{u}\|^2$  and  $F'(0) = f'(\bar{c}, \bar{u}) = 2\bar{c} \cdot \bar{u}$
6. Let  $f$  be linear, then  $f'(\bar{c}, \bar{u}) = f(\bar{u})$
7. Existence of all partial derivatives doesn't imply existence of all directional derivatives.

$$f(x, y) = \begin{cases} x + y & \text{if } x = 0 \text{ or } y = 0 \\ 1 & \text{otherwise} \end{cases}$$

For above  $f$ , directional derivatives exists only along the co-ordinates (ie, partial derivatives).

8. Existence of all directional derivatives doesn't imply continuity.

$$f(x, y) = \begin{cases} xy^2(x^2 + y^4) & x \neq 0 \\ 0 & x = 0 \end{cases}$$

Above  $f$  is discontinuous at  $(0, 0)$ , however all directional derivatives exists and has finite value.

## 17.2 Total Derivative

We may define a total derivative  $T_c(h) = hf'(c)$  in the case of real-functions of single variable as follows :-

$$\text{Let } E_c(h) = \begin{cases} \frac{f(c+h)-f(c)}{h} - f'(c), & h \neq 0 \\ 0, & h = 0 \end{cases}$$

Then,  $f(c+h) = f(c) + hf'(c) + hE_c(h)$  and as  $h \rightarrow 0$ ,  $E_c(h) \rightarrow 0$ . Also  $T_c(h) = f'(c)h$  is a linear function of  $h$ . ie,  $T_c(ah_1 + bh_2) = aT_c(h_1) + bT_c(h_2)$ . Now, we will define a total derivative of multivariate function that has these two properties.

**Definitions 17.2** (Total Derivative). The function  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is differentiable at  $\bar{c}$  if there exists a **linear** function  $T_{\bar{c}} : \mathbb{R}^n \rightarrow \mathbb{R}^m$  such that  $f(\bar{c} + \bar{v}) = f(\bar{c}) + T_{\bar{c}}(\bar{v}) + \|\bar{v}\|E_{\bar{c}}(\bar{v})$  where  $E_{\bar{c}}(\bar{v}) \rightarrow 0$  as  $\bar{v} \rightarrow \bar{0}$ .

The linear function  $T_{\bar{c}}$  is the total derivative of  $f$  at  $\bar{c}$ ,  $T_{\bar{c}}(\bar{0}) = \bar{0}$  and the condition above gives the First Order Taylor's Formula for  $f(\bar{c} + \bar{v}) - f(\bar{c})$ .

**Remark** (Properties). *Let  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  and  $f'(\bar{c})(\bar{v}) = T_{\bar{c}}(\bar{v})$  be the total derivative of  $f$  at  $\bar{c}$  evaluated at  $\bar{v}$ . Then,*

1.  $f'(\bar{c})(\bar{v}) = f'(\bar{c}, \bar{u})$
2. *If  $f$  is differentiable at  $\bar{c}$ , then  $f$  is continuous at  $\bar{c}$ .*
3.  $f'(\bar{c})(\bar{v}) = v_1 D_1 f(\bar{c}) + v_2 D_2 f(\bar{c}) + \cdots + v_n D_n f(\bar{c})$

**Note.** *The above  $f'$  is a function from  $\mathbb{R}^n$  to the set of all linear functions  $\mathcal{L} = \{h : \mathbb{R}^n \rightarrow \mathbb{R}^m\}$ .  $f'(\bar{c})$  is a linear function (in fact, total derivative  $T_{\bar{c}}$ ) which maps  $\bar{v}$  into the directional derivatives of  $f$  at  $\bar{c}$  in the direction  $\bar{v}$ . This notation generalises  $f'$  for univariate  $f$  as well. (put  $n = m = 1$ )*

*In this subject, we use the following notations,*

$D_k f(\bar{c})$  *partial derivative*

$f'(\bar{c}, \bar{v})$  *directional derivative*

$f'(\bar{c})(\bar{v})$  *total derivative*

$\nabla f(\bar{c})$  *gradient vector*

**Theorem 17.3.** *If  $f$  is differentiable at  $\bar{c}$  with total derivative  $T_{\bar{c}}$ , then for every  $\bar{u} \in \mathbb{R}^n$ ,  $T_{\bar{c}}(\bar{u}) = f'(\bar{c}, \bar{u})$ . ( ie,  $f'(\bar{c})(\bar{v}) = f'(\bar{c}, \bar{v})$  )*

*Proof.* For  $\bar{v} = \bar{0}$ , we have  $T_{\bar{c}}(\bar{0}) = 0 = f'(\bar{c}, \bar{0})$ .

Suppose  $\bar{v} \neq \bar{0}$ , then put  $\bar{v} = h\bar{u}$ . Since  $f$  is differentiable at  $\bar{c}$ ,  $f$  has total derivative at  $\bar{c}$ . That is, there exists a linear function  $T_{\bar{c}}$  such that  $f(\bar{c} + h\bar{u}) = f(\bar{c}) + T_{\bar{c}}(h\bar{u}) + \|h\bar{u}\| E_{\bar{c}}(h\bar{u})$  where  $E_{\bar{c}}(h\bar{u}) \rightarrow \bar{0}$  as  $h\bar{u} \rightarrow \bar{0}$ .

$$\begin{aligned}
 &\implies f(\bar{c} + h\bar{u}) = f(\bar{c}) + hT_{\bar{c}}(\bar{u}) + |h|\|\bar{u}\|E_{\bar{c}}(h\bar{u}), \quad E_{\bar{c}}(h\bar{u}) \rightarrow \bar{0} \text{ as } h\bar{u} \rightarrow \bar{0} \\
 &\implies \frac{f(\bar{c} + h\bar{u}) - f(\bar{c})}{h} = T_{\bar{c}}(\bar{u}) + \frac{|h|\|\bar{u}\|E_{\bar{c}}(h\bar{u})}{h}, \quad E_{\bar{c}}(h\bar{u}) \rightarrow \bar{0} \text{ as } h \rightarrow 0 \\
 &\implies \lim_{h \rightarrow 0} \frac{f(\bar{c} + h\bar{u}) - f(\bar{c})}{h} = T_{\bar{c}}(\bar{u}) + \lim_{h \rightarrow 0} \frac{|h|\|\bar{u}\|E_{\bar{c}}(h\bar{u})}{h} \\
 &\implies f'(\bar{c}, \bar{u}) = T_{\bar{c}}(\bar{u})
 \end{aligned}$$

□

**Note.**  $T_{\bar{c}}$  is linear, however  $E_{\bar{c}}$  is not linear. Thus  $E_{\bar{c}}(h\bar{u}) \neq hE_{\bar{c}}(\bar{u})$ .

As  $h \rightarrow 0$ ,  $h\bar{u} \rightarrow \bar{0}$  and  $E_{\bar{c}}(h\bar{u}) \rightarrow \bar{0}$ . Since the order of the function  $E_{\bar{c}}(h\bar{u})$  is much smaller than that of  $h$ , the limit on the right converges to 0.

**Theorem 17.4.** *If  $f$  is differentiable at  $\bar{c}$ , then  $f$  is continuous at  $\bar{c}$ .*

*Proof.* Let  $\bar{v} \neq 0$ , then

$$\begin{aligned}\bar{v} &= v_1 \bar{u}_1 + v_2 \bar{u}_2 + \cdots + v_n \bar{u}_n, \\ \bar{v} \rightarrow \bar{0} &\implies \forall j, v_j \rightarrow 0 \\ T \text{ is linear} &\implies T_{\bar{c}}(\bar{v}) = v_1 T_{\bar{c}}(\bar{u}_1) + v_2 T_{\bar{c}}(\bar{u}_2) + \cdots + v_n T_{\bar{c}}(\bar{u}_n) \\ \text{Thus, } T_{\bar{c}}(\bar{v}) &\rightarrow \bar{0} \text{ as } \bar{v} \rightarrow 0\end{aligned}$$

Since  $f$  differentiable at  $\bar{c}$ , there exists linear function  $T_{\bar{c}}$  such that

$$\begin{aligned}f(\bar{c} + \bar{v}) &= f(\bar{c}) + T_{\bar{c}}(\bar{v}) + \|\bar{v}\| E_{\bar{c}}(\bar{v}) \\ \implies \lim_{\bar{v} \rightarrow \bar{0}} f(\bar{c} + \bar{v}) &= f(\bar{c}) + \lim_{\bar{v} \rightarrow \bar{0}} T_{\bar{c}}(\bar{v}) + \lim_{\bar{v} \rightarrow \bar{0}} \|\bar{v}\| E_{\bar{c}}(\bar{v}) \\ \implies \lim_{\bar{v} \rightarrow \bar{0}} f(\bar{c} + \bar{v}) &= f(\bar{c})\end{aligned}$$

□

**Theorem 17.5.** Let  $S \subset \mathbb{R}^n$  and  $f : S \rightarrow \mathbb{R}^m$  be differentiable at an interior point  $\bar{c}$  of  $S$ , where  $S \subseteq \mathbb{R}^n$ . If  $\bar{v} = v_1 \bar{u}_1 + v_2 \bar{u}_2 + \cdots + v_n \bar{u}_n$ , then

$$f'(\bar{c})(\bar{v}) = \sum_{k=1}^n v_k D_k f(\bar{c})$$

In particular, if  $f$  is real-valued ( $m = 1$ ) we have,  $f'(\bar{c})(\bar{v}) = \nabla f(\bar{c}) \cdot \bar{v}$

*Proof.* Suppose  $f : S \rightarrow \mathbb{R}^m$  is differentiable at  $\bar{c}$ , then there exists a linear function  $f'(\bar{c}) : S \rightarrow \mathbb{R}^m$  such that  $f(\bar{c} + \bar{v}) = f(\bar{c}) + f'(\bar{c})(\bar{v}) + \|\bar{v}\| E_{\bar{c}}(\bar{v})$  where  $E_{\bar{c}} \rightarrow \bar{0}$  as  $\bar{v} \rightarrow \bar{0}$ .

$$\begin{aligned}f'(\bar{c})(\bar{v}) &= f'(\bar{c}) \left( \sum_{k=1}^n v_k \bar{u}_k \right) \\ &= \sum_{k=1}^n v_k f'(\bar{c})(\bar{u}_k), \text{ since } f'(\bar{c}) \text{ is linear} \\ &= \sum_{k=1}^n v_k D_k f(\bar{c}), \text{ since } f'(\bar{c})(\bar{u}_k) = f'(\bar{c}, \bar{u}_k) = D_k f(\bar{c})\end{aligned}$$

Let  $m = 1$ , then  $f : S \rightarrow \mathbb{R}$

$$\begin{aligned}f'(\bar{c})(\bar{v}) &= \sum_{k=1}^n v_k D_k f(\bar{c}) = \nabla f(\bar{c}) \cdot \bar{v} \\ \text{since } \nabla f(\bar{c}) &= (D_1 f(\bar{c}), D_2 f(\bar{c}), \dots, D_n f(\bar{c}))\end{aligned}$$

□

**Remark.** Let  $f : S \rightarrow \mathbb{R}$ , then  $f(\bar{c} + \bar{v}) = f(\bar{c}) + \nabla f(\bar{c}) \cdot \bar{v} + o(\|\bar{v}\|)$  as  $\bar{v} \rightarrow \bar{0}$ .

**Remark** (Complex-valued Functions). *Seminar - Rohitha*

### 17.3 Matrix of Linear Function

Let  $T : \mathbb{R}^n \rightarrow \mathbb{R}^m$  be a linear function. Let  $\{\overline{u_1}, \overline{u_2}, \dots, \overline{u_n}\}$  be standard basis for  $\mathbb{R}^n$  and  $\{\overline{e_1}, \overline{e_2}, \dots, \overline{e_m}\}$  be standard basis for  $\mathbb{R}^m$ . Let  $\overline{v} \in \mathbb{R}^n$ , then  $T(\overline{v}) = \sum_{k=1}^n v_k T(\overline{u_k})$  and

$$T(\overline{v}) = \begin{bmatrix} v_1 & v_2 & \cdots & v_n \end{bmatrix} T \begin{bmatrix} \overline{u_1} \\ \overline{u_2} \\ \vdots \\ \overline{u_n} \end{bmatrix} = \begin{bmatrix} v_1 & v_2 & \cdots & v_n \end{bmatrix} \begin{bmatrix} t_{11} & t_{12} & \cdots & t_{1n} \\ t_{21} & t_{22} & \cdots & t_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ t_{m1} & t_{m2} & \cdots & t_{mn} \end{bmatrix} \begin{bmatrix} \overline{e_1} \\ \overline{e_2} \\ \vdots \\ \overline{e_m} \end{bmatrix}$$

Thus matrix of the transformation,  $m(T) = (t_{ik})$  where  $T(\overline{u_k}) = \sum_{i=1}^m t_{ik} \overline{e_i}$ .

**Remark.** For example : Let  $T : \mathbb{R}^3 \rightarrow \mathbb{R}^2$  defined by  $T(x, y, z) = (2x + y, y - z)$ . Then

$$m(T) = \begin{bmatrix} 2 & 0 \\ 1 & 1 \\ 0 & -1 \end{bmatrix}, \quad T(1, 2, 3) = \begin{bmatrix} 1 & 2 & 3 \end{bmatrix} \begin{bmatrix} 2 & 0 \\ 1 & 1 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} \overline{e_1} \\ \overline{e_2} \end{bmatrix} = 4\overline{e_1} - \overline{e_2} = (4, -1)$$

## Networks

### 22.1 An Introduction to Networks

**Definitions 22.1.** A **network**  $N$  is a digraph  $D$  with two special vertices source  $s$  and sink  $t$  together with a capacity function  $c : E(D) \rightarrow \mathbb{Z}$  such that for every arc  $a = (u, v)$  of the digraph,  $c(u, v)$  is non-negative.

**Remark.** *Mathematical Modeling using Network,*

1. There is no restriction on indegree/outdegree of source/sink vertices of the digraph  $D$  of a network  $N$ .
2. Applications of Network : Transportation problem.

$c(u, v)$  is the capacity of the arc  $(u, v)$  of  $D$

$N^+(x) = \{y \in V(D) : (x, y) \in E(D)\}$  is the out-neighbourhood of  $x$ .

$N^-(x) = \{y \in V(D) : (y, x) \in E(D)\}$  is the in-neighbourhood of  $x$ .

**Definitions 22.2.** A **flow  $f$  in a network  $N$**  is function  $f : E(D) \rightarrow \mathbb{Z}$  such that 1. each edge satisfies capacity constraint and 2. each vertex except source and sink satisfies conservation equation.

**capacity constraint**

$$0 \leq f(a) \leq c(a) \text{ for every arc } a \in V(D) \quad (22.1)$$

**conservation equation**

$$\sum_{y \in N^+(x)} f(x, y) = \sum_{y \in N^-(x)} f(y, x), \quad \forall \text{ vertex } x \in V(D) - \{s, t\} \quad (22.2)$$

**net flow out of  $x$**

$$\sum_{y \in N^+(x)} f(x, y) - \sum_{y \in N^-(x)} f(y, x)$$

**net flow into  $x$**

$$\sum_{y \in N^-(x)} f(y, x) - \sum_{y \in N^+(x)} f(x, y)$$

**Definitions 22.3.** The **flow  $f$  in a network  $N$**  is the net flow out of source  $s$ .

**Remark.** 1. net flow out of/into  $x \in V(D) - \{s, t\}$  is zero.

2. Without loss of generality<sup>1</sup>, underlying digraph is always assymetric.

$(X, Y) = \{(x, y) \in E(D) : x \in X, y \in Y\}$ .

Let  $X, Y$  be non-empty subsets of  $V(D)$  such that  $X, Y$  are disjoint. Then  $(X, Y)$  is the set of all arcs from  $X$  to  $Y$ .

**flow from  $X$  to  $Y$**  is the sum of flow on each arc in  $(X, Y)$

$$f(X, Y) = \sum_{(x, y) \in (X, Y)} f(x, y) \quad (22.3)$$

**capacity of the partition  $(X, Y)$**  is the total capacity of arcs in  $(X, Y)$

$$c(X, Y) = \sum_{(x, y) \in (X, Y)} c(x, y) \quad (22.4)$$

**cut** Let  $P \subset V(D)$  such that  $s \in P$  and  $t \notin P$  and  $\bar{P} = V(D) - P$ , then  $(P, \bar{P})$  is a cut.

**flow from  $P$  to  $\bar{P}$**  is the sum of flow on each arc in  $(P, \bar{P})$ .

$$f(P, \bar{P}) = \sum_{(x, y) \in (P, \bar{P})} f(x, y) \quad (22.5)$$

**flow from  $\bar{P}$  to  $P$**  is the sum of flow on each arc in  $(\bar{P}, P)$

$$f(\bar{P}, P) = \sum_{(x, y) \in (\bar{P}, P)} f(x, y) \quad (22.6)$$

**capacity of the cut  $(P, \bar{P})$**  is the total capacity of the arcs in  $(P, \bar{P})$

$$c(P, \bar{P}) = \sum_{(x, y) \in (P, \bar{P})} c(x, y) \quad (22.7)$$

**Theorem 22.4.** For any cut  $(P, \bar{P})$ , the flow in  $N$  is  $f(N) = f(P, \bar{P}) - f(\bar{P}, P)$ .

**Synopsis.** The net flow out of source  $s$  is the flow  $f(N)$  in the network  $N$ . Let  $(P, \bar{P})$  be a cut of  $N$ , then  $s \in P$  and  $t \notin P$ . Suppose  $P = \{s\}$ , then the theorem is true. Suppose  $P$  is not singleton, then for each vertex  $x \in P$ ,  $x \neq s$ , the net flow out of  $x$  is zero by flow conservation equation. And flow between vertices in  $P$  cancels out each other. Thus adding net flow out of each vertex in  $P$ , will be same as the net flow out of source which is the flow in the network,  $f(N)$ .

<sup>1</sup>If underlying digraph of a network is symmetric, then by replacing an arc  $(u, v)$  with a new vertex  $w$  and two arcs  $(u, w), (w, v)$  gives an assymetric digraph.[Gray Chartrand, ]pp.131

*Proof.*

$$\text{Flow, } f = \sum_{y \in N^+(s)} f(s, y) - \sum_{y \in N^-(s)} f(y, s) \quad (22.8)$$

By conservation equation, we have  $\forall x \in P, x \neq s$ ,

$$\sum_{y \in N^+(x)} f(x, y) - \sum_{y \in N^-(x)} f(y, x) = 0 \quad (22.9)$$

By above equations,

$$\begin{aligned} \text{Flow, } f &= \sum_{x \in P} \sum_{y \in N^+(x)} f(x, y) - \sum_{x \in P} \sum_{y \in N^-(x)} f(y, x) \\ &= \sum_{(x, y) \in (P, \bar{P})} f(x, y) - \sum_{(y, x) \in (\bar{P}, P)} f(y, x) \end{aligned} \quad (22.10)$$

□

**Corollary 22.4.1.** *Flow cannot exceed the capacity of any cut  $(P, \bar{P})$ . Further,  $f(N) \leq \min c(P, \bar{P})$ .*

**Synopsis.** *Let  $(P, \bar{P})$  be a cut in network  $N$ , then by theorem the flow  $f(N) = \text{flow from } P \text{ to } \bar{P} - \text{flow from } \bar{P} \text{ to } P$ . Since the flow from  $\bar{P}$  to  $P$  is non-negative,  $f(N) \leq \text{flow from } P \text{ to } \bar{P}$ . Clearly,  $f(x, y) \leq c(x, y)$  by the capacity constraint. Thus  $f(N) \leq f(P, \bar{P}) \leq c(P, \bar{P}) \leq \min c(P, \bar{P})$ .*

*Proof.*

$$\begin{aligned} f(N) &= \sum_{(x, y) \in (P, \bar{P})} f(x, y) - \sum_{(y, x) \in (\bar{P}, P)} f(y, x) \\ &\leq \sum_{(x, y) \in (P, \bar{P})} f(x, y) = f(P, \bar{P}) \\ &\leq \sum_{(x, y) \in (P, \bar{P})} c(x, y) = c(P, \bar{P}), \quad \because \forall x, y \in V(D), f(x, y) \leq c(x, y) \\ &\leq \min c(P, \bar{P}) \end{aligned}$$

□

**Corollary 22.4.2.** *In a network  $N$  flow is the net flow into the sink of  $N$ .*

**Synopsis.** *Let  $\bar{P} = \{t\}$ , then by theorem  $f(N)$  is the net flow into the sink.*

*Proof.* Suppose  $P = V(D) - \{t\}$ . Then by theorem, we have

$$\begin{aligned} f(N) &= \sum_{(x, y) \in (P, \bar{P})} f(x, y) - \sum_{(y, x) \in (\bar{P}, P)} f(y, x) \\ &= \sum_{x \in N^-(t)} f(x, t) - \sum_{x \in N^+(t)} f(t, x) \end{aligned}$$

□

**Remark.** *Exercise 5.1*

4. Let  $N$  be a network with underlying digraph  $D$  which has a vertex  $v \in V(D) - \{s, t\}$  with zero indegree. Clearly the flow into  $v$  is zero. Thus flow out of  $v$  is also zero by flow conservation equation. Let  $N'$  be the network obtained from  $N$  by deleting the vertex  $v$ . Then  $f(N) = f(N')$ .

## 22.2 The Max-Flow Min-Cut Theorem

**maximum flow** A flow  $f$  in network  $N$  is maximum flow in  $N$ , if  $f(N) \geq f'(N)$  for each flow  $f'$  in  $N$ .

**minimum cut** A cut  $(P, \bar{P})$  in network  $N$  is minimum cut of  $N$ , if  $c(P, \bar{P}) \leq c(X, \bar{X})$  for each cut  $(X, \bar{X})$  in  $N$ .

**$f$ -unsaturated** Let  $f$  be a flow in network  $N$  with underlying digraph  $D$ , and  $Q = u_0, a_1, u_1, a_2, \dots, u_{n-1}, a_n, u_n$  be a semipath in  $D$  such that every forward arc  $a_i = (u_{i-1}, u_i)$  has flow not upto its capacity,  $f(a_i) < c(a_i)$  and every reverse arc  $a_i = (u_i, u_{i-1})$  has some positive flow in it,  $f(a_i) > 0$

**$f$ -augmenting semipath** Let  $f$  be a flow in a network  $N$  with underlying digraph  $D$ . Suppose semipath  $Q = s, a_1, u_1, a_2, \dots, u_{n-1}, a_n, t$  (from source to sink) is  $f$ -unsaturated, then  $Q$  is an  $f$ -augmenting semipath.

**Theorem 22.5.** Let  $f$  be a flow in a network  $N$  with underlying digraph  $D$ . The flow  $f$  is maximum in  $N$  iff there is no  $f$ -augmenting semipath in  $D$ .

**Synopsis.** Suppose  $Q$  is an  $f$ -augmenting semipath in  $D$ , then there exists a flow  $f^*$  in  $N$  such that  $f(N) + \Delta = f^*(N)$ . Therefore,  $f$  is not a maximum flow in  $N$ . Suppose there is no  $f$ -augmenting semipath in  $D$ , then there exists a cut  $(P, \bar{P})$  such that  $f(a) = c(a) \forall a \in (P, \bar{P})$  and  $f(a) = 0 \forall a \in (\bar{P}, P)$ . Suppose  $f^*$  in a maximum flow in  $N$ , then  $f(N) \leq f^*(N) \leq c(P, \bar{P}) = f(N)$ .

*Proof.* Let  $f$  be a flow in a network  $N$  with underlying digraph  $D$  and  $Q = s, a_1, u_1, a_2, u_2, \dots, u_{n-1}, a_n, t$  be an  $f$ -augmenting semipath in  $D$ .

$$\text{define } \Delta_i = \begin{cases} c(a_i) - f(a_i) & \text{for every forward arc } a_i \in Q, \\ f(a_i) & \text{for every reverse arc } a_i \in Q, \end{cases}$$

Define  $\Delta = \min\{\Delta_i\}$ . Also define  $f^* : E(D) \rightarrow \mathbb{Z}$  such that

$$f^*(a_i) = \begin{cases} f(a_i) + \Delta, & \text{for every forward arc } a_i \in Q, \\ f(a_i) - \Delta, & \text{for every reverse arc } a_i \in Q, \\ f(a_i), & \text{for every arc of } D \text{ which are not in } Q. \end{cases}$$

Since  $Q$  is an  $f$ -augmenting semipath in  $D$ ,  $\Delta > 0$  and  $f(N) + \Delta = f^*(N)$ .

Clearly  $f(N) < f^*(N)$ , and it is enough to show that  $f^*$  is a flow in  $N$ .  $f^*$  is a flow if it satisfies 1. capacity constraint and 2. conservation equation. For any arc  $a_i \notin Q$ ,  $f^*(a_i) = f(a_i) \leq c(a_i)$ . Suppose  $a_i \in Q$ . If  $a_i = (u_{i-1}, u_i)$ ,  $a_i$  is a forward arc and we have  $f^*(a_i) = f(a_i) + \Delta \leq f(a_i) + \Delta_i = f(a_i) + c(a_i) - f(a_i) = c(a_i)$ . If  $a_i = (u_i, u_{i-1})$ , then  $a_i$  is a reverse arc and we have  $f^*(a_i) = \Delta \leq \min\{\Delta_i\} = \Delta_i = c(a_i)$ . Thus  $f^*$  satisfies capacity constraint on every arc of  $D$ .

Let  $x \in V(D) - \{s, t\}$ . Suppose  $x \notin Q$ ,

$$\begin{aligned} \text{Net flow out of } x &= \sum_{y \in N^+(x)} f^*(x, y) - \sum_{y \in N^-(x)} f^*(y, x) \\ &= \sum_{y \in N^+(x)} f(x, y) - \sum_{y \in N^-(x)} f(y, x) \\ &= 0 \end{aligned}$$

Suppose  $x = u_i \in Q$ , then  $Q$  has two arc having vertex  $x$  say,  $a_{i-1}$ , and  $a_i$ . There are four possibilities for these two arcs,

1. Both  $a_{i-1}$ ,  $a_i$  are forward arcs.
2. Arc  $a_{i-1}$  is forward, but arc  $a_i$  is reverse.
3. Arc  $a_{i-1}$  is reverse, but arc  $a_i$  is forward.
4. Both  $a_{i-1}$ ,  $a_i$  are reverse arcs.

**Case 1**  $a_{i-1} = (u_{i-1}, u_i)$  and  $a_i = (u_i, u_{i+1})$ .

$$\begin{aligned} \text{Net flow out of } x &= \sum_{y \in N^+(x)} f^*(x, y) - \sum_{y \in N^-(x)} f^*(y, x) \\ &= \sum_{\substack{y \in N^+(x) \\ y \neq u_{i+1}}} f^*(x, y) + f^*(u_i, u_{i+1}) - \left( \sum_{\substack{y \in N^-(x) \\ y \neq u_{i-1}}} f^*(y, x) + f^*(u_{i-1}, u_i) \right) \\ &= \sum_{\substack{y \in N^+(x) \\ y \neq u_{i+1}}} f(x, y) + f(u_i, u_{i+1}) + \Delta - \left( \sum_{\substack{y \in N^-(x) \\ y \neq u_{i-1}}} f(y, x) + f(u_{i-1}, u_i) \right) - \Delta \\ &= \sum_{y \in N^+(x)} f(x, y) - \sum_{y \in N^-(x)} f(y, x) \\ &= 0 \end{aligned}$$

**Case 2**  $a_{i-1} = (u_{i-1}, u_i)$  and  $a_i = (u_{i+1}, u_i)$ .

$$\begin{aligned} \text{Net flow out of } x &= \sum_{y \in N^+(x)} f^*(x, y) - \sum_{y \in N^-(x)} f^*(y, x) \\ &= \sum_{\substack{y \in N^+(x) \\ y \neq u_{i+1}, u_{i-1}}} f^*(x, y) + f^*(u_i, u_{i+1}) + f^*(u_i, u_{i-1}) - \sum_{y \in N^-(x)} f^*(y, x) \\ &= \sum_{\substack{y \in N^+(x) \\ y \neq u_{i+1}, u_{i-1}}} f(x, y) + f(u_i, u_{i+1}) + \Delta + f(u_i, u_{i-1}) - \Delta - \sum_{y \in N^-(x)} f(y, x) \\ &= \sum_{y \in N^+(x)} f(x, y) - \sum_{y \in N^-(x)} f(y, x) \\ &= 0 \end{aligned}$$

**Case 3**  $a_{i-1} = (u_i, u_{i-1})$  and  $a_i = (u_i, u_{i+1})$ .

$$\begin{aligned}
\text{Net flow out of } x &= \sum_{y \in N^+(x)} f^*(x, y) - \sum_{y \in N^-(x)} f^*(y, x) \\
&= \sum_{y \in N^+(x)} f^*(x, y) - \left( \sum_{\substack{y \in N^-(x) \\ y \neq u_{i-1}, u_{i+1}}} f^*(y, x) + f^*(u_{i-1}, u_i) + f^*(u_{i+1}, u_i) \right) \\
&= \sum_{y \in N^+(x)} f^*(x, y) - \left( \sum_{\substack{y \in N^-(x) \\ y \neq u_{i-1}, u_{i+1}}} f(y, x) + f(u_{i-1}, u_i) + \Delta + f(u_{i+1}, u_i) - \Delta \right) \\
&= \sum_{y \in N^+(x)} f(x, y) - \sum_{y \in N^-(x)} f(y, x) \\
&= 0
\end{aligned}$$

**Case 4**  $a_{i-1} = (u_i, u_{i-1})$  and  $a_i = (u_{i+1}, u_i)$ .

$$\begin{aligned}
\text{Net flow out of } x &= \sum_{y \in N^+(x)} f^*(x, y) - \sum_{y \in N^-(x)} f^*(y, x) \\
&= \sum_{\substack{y \in N^+(x) \\ y \neq u_{i-1}}} f^*(x, y) + f^*(u_i, u_{i-1}) - \left( \sum_{\substack{y \in N^-(x) \\ y \neq u_{i+1}}} f^*(y, x) + f^*(u_{i+1}, u_i) \right) \\
&= \sum_{\substack{y \in N^+(x) \\ y \neq u_{i-1}}} f(x, y) + f(u_i, u_{i-1}) - \Delta - \left( \sum_{\substack{y \in N^-(x) \\ y \neq u_{i+1}}} f(y, x) + f(u_{i+1}, u_i) \right) + \Delta \\
&= \sum_{y \in N^+(x)} f(x, y) - \sum_{y \in N^-(x)} f(y, x) \\
&= 0
\end{aligned}$$

Therefore,  $f^*$  is a flow on  $N$ . We have  $f(N) < f^*(N)$ . Thus  $f$  is not maximum flow in  $N$  due to the existence of an  $f$ -augmenting semipath in  $D$ .

Conversely, assume that there is no  $f$ -augmenting semipath in  $D$ . Now, we construct a cut  $(P, \bar{P})$  of  $N$ . Let  $P$  be the set of all vertices  $x \in V(D)$  such that there is an  $f$ -unsaturated  $s - x$  semipath in  $D$ . Trivially,  $s \in P$ . And  $t \notin P$  since there are no  $f$ -augmenting semipath in  $D$ .<sup>2</sup> Clearly,  $(P, \bar{P})$  is a cut of the network  $N$ .

We claim that  $c(P, \bar{P}) = f(N)$ . Suppose there is a forward arc  $(x, y) \in (P, \bar{P})$ , then flow in it is saturated. If  $f(x, y) < c(x, y)$ , then there is an  $f$ -unsaturated  $s - y$  semipath in  $D$ . ie,  $s - x$  semipath + arc  $(x, y)$ . Thus every forward arc  $(x, y) \in (P, \bar{P})$  is saturated. Suppose there is a reverse arc  $(y, x) \in$

---

<sup>2</sup>An  $f$ -augmenting semipath is an  $f$ -unsaturated  $s - t$  semipath in  $D$ .

$(\bar{P}, P)$ , then there is no flow in it (saturated reversed arc). If  $f(y, x) > 0$ , then there is an  $f$ -unsaturated  $s - y$  semipath in  $D$ . ie,  $s - x$  semipath + arc  $(y, x)$ . Thus every reverse arc  $(y, x) \in (\bar{P}, P)$  is saturated. And we have,

$$\begin{aligned} \sum_{(x,y) \in (P, \bar{P})} f(x, y) &= \sum_{(x,y) \in (P, \bar{P})} c(x, y) \\ \sum_{(y,x) \in (\bar{P}, P)} f(y, x) &= 0 \\ f(N) &= \sum_{(x,y) \in (P, \bar{P})} f(x, y) - \sum_{(y,x) \in (\bar{P}, P)} f(y, x) \\ &= \sum_{(x,y) \in (P, \bar{P})} c(x, y) \\ &= c(P, \bar{P}) \end{aligned}$$

Suppose  $f^*$  is maximum flow in network  $N$  and  $(X, \bar{X})$  is minimum cut of  $N$ . Then  $f(N) \leq f^*(N)$ . Thus we have,  $f(N) \leq f^*(N) \leq c(X, \bar{X}) \leq c(P, \bar{P}) = f(N)$ . Therefore,  $f(N) = f^*(N)$ . ie, the flow  $f$  is maximum in network  $N$  if there are no  $f$ -augmenting semipaths in  $D$ .  $\square$

**Theorem 22.6** (maximum-flow, min-cut). *In every network, the value of maximum flow equals capacity of minimum cut.*

*Proof.* Suppose flow  $f$  in network  $N$  is maximum, then by previous theorem there is no  $f$ -augmenting semipath in  $D$ . And  $f(N) \leq c(X, \bar{X})$  for any cut  $(X, \bar{X})$  in  $N$ . We can construct a cut  $(P, \bar{P})$  in  $N$  such that  $f(N) = c(P, \bar{P})$ . Let  $P$  be the set of all vertices  $x$  in  $D$  such that there is an  $f$ -unsaturated  $s - x$  semipath in  $D$ . Clearly  $s \in P$  and  $t \notin P$ . Also  $f(P, \bar{P}) = c(P, \bar{P})$  and  $f(\bar{P}, P) = 0$ . Then the cut  $(P, \bar{P})$  is minimum cut of  $N$ . Suppose there is a cut  $(X, \bar{X})$  such that  $c(X, \bar{X}) < c(P, \bar{P})$ . Then  $f(N) = f(P, \bar{P}) - f(\bar{P}, P) = c(P, \bar{P}) < c(X, \bar{X})$  which is a contradiction. Therefore, the value of maximum flow equals capacity of minimum cut.  $\square$

**Remark.** Exercise 5.2

1. Suppose  $(X, \bar{X})$  is a cut of  $N$  such that  $f(a) = c(a)$ ,  $\forall a \in (X, \bar{X})$  and  $f(a) = 0$ ,  $\forall a \in (\bar{X}, X)$ . By the definition of cut,  $s \in X$  and  $t \in \bar{X}$ . Thus there is no  $f$ -augmenting semipath in  $D$ . Suppose there is an  $f$ -augmenting semipath  $Q$  in  $D$ , then there is either (a) a forward arc  $(x, y) \in (X, \bar{X})$  such that  $f(x, y) < c(x, y)$  or (b) a reverse arc  $(y, x) \in (\bar{X}, X)$  such that  $f(y, x) > 0$  which is a contradiction. Therefore, the flow  $f(N)$  is maximum and the given cut  $(X, \bar{X})$  is minimum as shown in the proof of the maximum-flow min-cut theorem.
3. The algorithm suggested in the hint of this exercise won't work if two subnetworks have a common arc such that the direction of flow in which is not consistent. Suppose, the generalized network is not supposed to have any common arcs. Then construct subnetworks for each pair  $(s, t)$  with all those arcs which are on some  $s - t$  semipath. Define subnetwork capacity function  $c'(a) = c(a)$  for every arc in  $N'$ .

Let  $N$  be a generalized network with set of sources  $S$  and set of sinks  $T$ . A flow in  $N$  is maximum if there is not  $f$ -augmenting  $s-t$  semipath for each pair  $(s, t) \in S \times T$ .

## 22.3 A max-flow min-cut algorithm

**Theorem 22.7.** Let  $N$  be a network with underlying digraph  $D$ , source  $s$ , sink  $t$ , capacity function  $c$  and flow  $f$ . Let  $D'$  be the digraph with same vertex set as  $D$  and arc set defined by  $E(D') = \{(x, y) : (x, y) \in E(D), c(x, y) > f(x, y) \text{ or } (y, x) \in E(D), f(y, x) > 0\}$ . ie,  $D'$  has only the unsaturated arcs of  $D$ . Then  $D'$  has an  $s-t$  directed path iff  $D$  has an  $f$ -augmenting semipath. Moreover, shortest  $s-t$  path in  $D'$  has the same length as shortest  $f$ -augmenting semipath in  $D$ .

**Synopsis.** Each directed  $s-t$  path in  $D'$  has respective  $f$ -augmenting semipath in  $D$  and vice versa. Clearly, they have the same length.

*Proof.* Let  $N$  be a network with underlying digraph  $D$ , capacity  $c$  and flow  $f$ . Let  $D'$  be the digraph with vertex set  $V(D') = V(D)$  and arc set  $E(D') = \{(x, y) : \text{either } (x, y) \text{ or } (y, x) \text{ is unsaturated in } N\}$ .

Suppose  $D'$  has a directed  $s-t$  path  $Q' : s, u_1, u_2, \dots, u_{n-1}, t$ . Then by the construction of  $D'$ , for each  $u_i \in Q$ , there exists an  $f$  unsaturated arc  $a_i$  in  $D$ . ie, either forward arc  $a_i = (u_{k-1}, u_k)$  such that  $f(u_{k-1}, u_k) < c(u_{k-1}, u_k)$  or reverse arc  $a_i = (u_k, u_{k-1})$  such that  $f(u_k, u_{k-1}) > 0$ . Therefore, we have an  $s-t$  semipath  $Q : s, a_1, u_1, a_2, \dots, u_{n-1}, a_n, t$  in  $D$  such that  $Q$  is an  $f$ -augmenting semipath since every arc in  $Q$  is  $f$ -unsaturated. Clearly,  $Q, Q'$  are of the same length.

Conversely, suppose that the digraph  $D$  has an  $f$ -augmenting semipath  $Q : s, a_1, u_1, a_2, \dots, u_{n-1}, a_n, t$ . Then each arc  $a_i \in Q$  are  $f$ -unsaturated and by the construction of  $D'$ , there exists a directed  $s-t$  path  $Q' = s, u_1, u_2, \dots, u_{n-1}, t$  in  $D'$ . And  $Q, Q'$  are of the same length.

There is a one-one correspondence between the directed  $s-t$  paths in  $D'$  and  $f$ -augmenting semipaths in  $D$ . Clearly, they have the same length. Thus shortest directed  $s-t$  path in  $D$  and shortest  $f$ -augmenting semipath in  $D'$  are of the same length.  $\square$

**saturation arc** of  $N$  with respect to the flow  $f$  is an arc  $a_j$  in an  $f$ -augmenting semipath  $Q$  with  $\Delta_j = \Delta$ .

**augmentation path** is an  $f$ -augmenting semipath  $Q$  in  $D$ .

**Algorithm 22.8** (max-flow min-cut). An algorithm to find maximum flow and minimum cut of a network  $N$  with underlying digraph  $D$ , source  $s$ , sink  $t$ , capacity function  $c$  and initial flow  $f$ .

1. Construct digraph  $D'$  with vertex set  $V(D') = V(D)$  and arc set  $E(D') = \{(x, y) : (x, y) \in E(D) \& f(x, y) < c(x, y) \text{ or } (y, x) \in E(D) \& f(y, x) > 0\}$

2. Find (shortest)  $s-t$  directed path in  $D'$  using Moore's breadth first search(BFS) algorithm. If  $D'$  doesn't have an  $s-t$  path, then proceed to step 5. Otherwise, let  $Q' : s, u_1, u_2, \dots, u_{n-1}, t$  be a (shortest)  $s-t$  path in  $D'$ .
3. Let  $Q : s, a_1, u_1, a_2, \dots, u_{n-1}, a_n, t$  be the respective semipath in  $D$  such that  $f(a_j) < c(a_j)$  for forward arcs and  $f(a_i) > 0$  for reverse arcs. Let  $\Delta_j = c(a_j) - f(a_j)$  for forward arcs and  $\Delta_j = f(a_j)$  for reverse arcs. And let  $\Delta = \min\{\Delta_j\}$ . And augment flow  $f$  by  $\Delta$  ie,  $f(a_j) \leftarrow f(a_j) + \Delta$  for forward arcs and  $f(a_j) \leftarrow f(a_j) - \Delta$  for reverse arcs.
4. Goto step 1 (Proceed with new flow  $f$  and find whether there are any directed  $s-t$  paths in  $D'$ . If any, augment the flow along the new augmentation path  $Q$  by saturating the flow along the saturation arc.)
5. There is no  $s-t$  directed path in  $D'$ . Thus there is no  $f$ -augmenting semipath in  $D$ . Therefore the flow  $f$  in  $N$  is maximum. Let  $P$  be the set of all vertices in  $D'$  with non-zero breadth first index(bfi) from Moore's BFS algorithm applied in step 2.  $(P, \bar{P})$  is minimum cut of  $N$ .

**Remark.** Validity of the algorithm is proved in the previous theorem.

## 22.5 Connectivity and Edge-Connectivity

**edge cutset** is the set  $U$  subset of  $E(G)$  such that  $G - U$  is disconnected.

**vertex cutset** is the set  $S$  subset of  $V(G)$  such that  $G - S$  is disconnected.

**edge connectivity**  $\lambda(G)$  is the minimum cardinality of all edge cutsets of  $G$ .

**connectivity**  $\kappa(G)$  is the minimum cardinality of all vertex cutsets of  $G$ .

**Theorem 22.9.** For every graph  $G$ ,  $\kappa(G) \leq \lambda(G) \leq \delta(G)$

*Proof.* Suppose graph  $G$  is disconnected then  $\kappa(G) = \lambda(G) = \delta(G) = 0$ . Let  $G$  be a connected graph. Then  $G$  has at least one vertex  $v$  with degree  $\delta(G)$ . Therefore  $\lambda(G) \leq \delta(G)$  since edges incident with  $v$  form an edge cutset of  $G$  and  $\lambda(G)$  is the cardinality of all edge cutsets.

Let  $G$  be a graph with edge connectivity  $\lambda(G) = c$ . Let  $U$  be a edge cutset with cardinality  $c$  and let edge  $uv \in U$ . Construct a set of vertices  $S \subset V(G)$  such that ( $S$  is of minimal cardinality and) for each edge in  $U$  other  $uv$ ,  $S$  has a vertex incident with it. Cardinality of  $S$  is atmost  $c - 1$ , since we can select one vertex each for each edge in  $U$  other than  $u, v$ . If  $G - S$  is a disconnected graph, then  $\kappa(G) < \lambda(G)$ . Suppose  $G - S$  is a connected graph, then delete a non-pendent vertex  $u$  or  $v$  from  $G - S$ , say  $v$ . Since  $G - S$  is a connected graph with a singleton edge cutset,  $\{uv\}$ . We have a vertex cutset  $S \cup \{v\}$  of  $G$ . Therefore,  $\kappa(G) \leq c = \lambda(G)$ .  $\square$

**Theorem 22.10.** If  $G$  is a graph of diameter 2, then  $\lambda(G) = \delta(G)$

**$n$ -edge connected**  $G$  is  $n$ -edge connected if  $\lambda(G) \geq n$ .

**$n$  connected**  $G$  is  $n$ -connected if  $\kappa(G) \geq n$ .

**Theorem 22.11.** *Let  $G$  be a graph of order  $p$  and  $n$  be an integer such that  $1 \leq n \leq p-1$ . If  $\delta(G) \geq \frac{p+n-2}{2}$ , then  $G$  is  $n$ -connected.*

**connection number**  $c(G)$  is the smallest integer such that  $2 \leq c(G) \leq p$  and every subgraph of order  $n$  in  $G$  is connected.

**$l$ -connectivity**  $\kappa_l(G)$  is minimum number of vertices whose removal will produce a disconnected graph with at least  $l$  components or a graph with fewer than  $l$  vertices.

**$(n, l)$ -connected** A graph  $G$  is  $(n, l)$ -connected if  $\kappa_l(G) \geq n$ .

**Remark.** *Exercises 5.5*

$$1. \lambda(K_{m,n}) = \kappa(K_{m,n}) = m$$

$$8. c(K_p) = 2, c(K_{m,n}) = n+1, c(C_p) = p-1$$

*Every two vertices of complete graph of order  $p$  are adjacent. For complete bi-partite graph  $K_{m,n}$  such that  $1 \leq m \leq n$ , there exists a totally disconnected subgraph of order  $n$ . Therefore  $c(K_{m,n}) \geq n+1$ . And with  $n+1$  vertices, both partitions have at least two vertices each and therefore the graph is connected and  $c(K_{m,n}) \leq n+1$ . For cycle  $C_p$ , any subgraph is disconnected if two non-adjacent vertices are deleted. Therefore  $c(C_p) \geq p-1$ . And  $C_p$  remains connected even after deletion of any vertex, therefore  $c(C_p) \leq p-1$ .*

9.

$$\delta(G) \geq \frac{p + (l-1)(n-2)}{l} \implies \kappa_l(G) \geq n$$

## 22.6 Menger's Theorem

**Theorem 22.12.** *For a non-trivial graph  $G$ ,  $\lambda(u, v) = M'(u, v)$  for every pair  $(u, v)$  of vertices of  $G$ .*

**Corollary 22.12.1.** *Graph  $G$  is  $n$ -edge connected iff every two vertices of  $G$  are connected by at least  $n$  edge disjoint paths.*

**Theorem 22.13.** *For every pair of non-adjacent vertices  $u, v$  in graph  $G$ ,  $\kappa(u, v) = M(u, v)$ .*

**Corollary 22.13.1.** *Graph  $G$  is  $n$ -connected iff every pair of vertices of  $G$  are connected by at least  $n$  internally disjoint paths.*

**Algorithm 22.14** (connectivity  $\kappa(G)$ ). .

1. If degree of every vertex is  $p-1$ , then output  $\kappa = p-1$  and stop. Otherwise, continue.
2. If  $G$  is disconnected, output  $\kappa = 0$  and stop. Otherwise, continue.
3.  $\kappa \leftarrow p$
4.  $i \leftarrow 0$

5. If  $i \leq \kappa$ , then  $i \leftarrow i + 1$  and continue. Otherwise, output  $\kappa$  and stop.
6.  $j \leftarrow i + 1$
7. (1) If  $j = p + 1$ , then return to step 5. Otherwise continue.
  - (2) If  $v_i v_j \notin E(G)$ , construct network  $N$  with digraph  $D$  as follows :  
 for each vertex  $v \in V(G)$ , there are two vertices  $v', v'' \in V(D)$  and  
 an arc  $(v', v'') \in E(D)$ . And for each edge  $uv \in E(G)$ , there are  
 two arcs  $(u'', v), (v'', u) \in E(D)$ . The capacity function is given by,  
 $c(v', v'') = 1$  for every  $v \in V(G)$  and  $c(a) = \infty$  for every other arc  
 in  $D$ . Set source  $s = v''_i$  and sink  $t = v'_j$  and find maximum flow in  
 $N$  using max-flow min-cut algorithm. Otherwise proceed to step 7d
  - (3) If  $f(N) < \kappa$ , then  $\kappa \leftarrow f(N)$ . Otherwise, continue.
  - (4)  $j \leftarrow j + 1$  and return to step 7a

## Chapter 23

# Matchings and Factorizations

### 23.1 An Introduction to Matching

**Marriage Problem** Given a collection of men and women, where each woman knows some of the men. Can every woman marry a man she knows ?

**Assignment Problem** Given several job openings and applicants for one or more of these positions. Find an assignment so that maximum positions are filled ?

**Optimal Assignment Problem** Given several job openings and applicants for one or more of these positions. The benefits of employing these applicants on those positions are also given. Find an assignment of maximum benefit to the company ?

**matching** in  $G$  is a 1-regular<sup>1</sup> subgraph of  $G$ .

**maximum matching** in  $G$  is a matching of  $G$  with maximum cardinality.

**perfect matching** in  $G$  is a matching of cardinality  $p/2$ . ie,  $p/2$  edges.

**maximum weight matching** in a weighted graph  $G$  is a matching with maximum weight.

**Definitions 23.1.** Let  $M$  be a matching in a graph  $G$ ,

**matched edge** is an edge in subgraph  $M$  of  $G$ .

**unmatched edge** is an edge of  $G$  that doesn't belong to  $M$ .

**matched vertex** with respect to  $M$  is a vertex incident with an edge of  $M$ .

**single vertex** is a vertex that is not incident with any edge of  $M$ .

**alternating path** in  $G$  is a path with edges alternately matched and unmatched.

---

<sup>1</sup>A graph  $G$  is  $k$ -regular, if every vertex of  $G$  has degree  $k$ .

**augmenting path** in  $G$  is a non-trivial alternating path with single vertices as end vertices.

**Theorem 23.2.** Let  $M_1, M_2$  be two matchings in  $G$  such that there is a spanning subgraph  $H$  of  $G$  with edges that are either in  $M_1$  or  $M_2$ , but not both. Then the components of  $H$  are either 1. isolated vertex 2. even cycle with edge alternately from  $M_1$  and  $M_2$  3. a non-trivial path with edges alternately from  $M_1$  and  $M_2$  such that each end vertex is single with respect to either  $M_1$  or  $M_2$ , but not both.

**Synopsis.**  $\Delta(H) \leq 2$  by Pigeonhole principle. Any component of  $H$  is either a path or a cycle. A cycle with edge alternately from  $M_1$  and  $M_2$  is even. If an end vertex of a non-trivial path is matched with respect to  $M_1$  (WLOG), then it is there in  $M_1 - M_2$  ie, it is not there in  $M_2$ . If there is another edge in  $M_2$  incident with it, then it has to be in  $H$  and it will cease to be an end vertex of path component. Therefore, it is unmatched with respect to  $M_2$ .

**Theorem 23.3.** A matching  $M$  in a graph  $G$  is maximum iff there is no augmenting path with respect to  $M$  in  $G$ .

**Synopsis.** If  $M$  is maximum matching and  $P$  an  $M$ -augmenting path. Since both end-vertices are single, length of  $P$  is odd. Let  $M', M''$  be edges of  $P$  which are in  $M$  and not in  $M$  respectively. Then  $M - M' + M''$  is a matching of cardinality one greater than that of  $M$  which is a contradiction since  $M$  is maximum. Conversely, suppose  $M$  be a matching such that there no  $M$ -augmenting paths in  $G$ . Let  $M'$  be a maximum matching in  $G$ . Then a nontrivial path component of the graph induced by  $M \Delta M'$  is of even length otherwise both end-vertices are matched with respect to one of the matching  $M$  or  $M'$  which is a contradiction. Again every cycle components are even. Therefore  $|M| = |M'|$ , since  $M \Delta M'$  doesn't have a nontrivial component of another kind.

**Definitions 23.4.** Let  $U_1, U_2$  be two nonempty, disjoint, subsets of the vertex set of a graph  $G$ . Then  $U_1$  is **matched to**  $U_2$  if there exists a matching  $M$  in  $G$  such that every edge in  $M$  incident with a vertex in  $U_1$  and a vertex in  $U_2$ . And every vertex of  $U_1$  (or  $U_2$ ) is incident with some edge in  $M$ . Suppose  $M^*$  be a matching such that  $M \subset M^*$ , then  $U_1$  is **matched under  $M^*$  to**  $U_2$ .

**Definitions 23.5.** Let  $U$  be a nonempty set of vertices of a graph  $G$ .  $U$  is **nondeficient**,<sup>2</sup> if  $|N(S)| \geq |S|$  for every nonempty subset  $S$  of  $U$ .

**Theorem 23.6.** Let  $G$  be a bipartite graph with partite sets  $V_1, V_2$ . The set  $V_1$  can be matched to a subset of  $V_2$  iff  $V_1$  is nondeficient.

**Corollary 23.6.1.** Every  $r$ -regular bipartite multigraph has a perfect matching.

**Theorem 23.7.** A collection  $S_1, S_2, \dots, S_n$  of finite non-empty sets has a system of distinct representatives iff for each  $k$ ,  $0 \leq k \leq n$ , the union of any  $k$  of these sets contains at least  $k$  elements.

**Remark** (Hall's Marriage Theorem). Suppose there are  $n$  women. Then every women can marry a man she knows iff each subset of  $k$  women ( $1 \leq k \leq n$ ) collectively knows atleast  $k$  men.

**Remark.** Let  $W$  be a set of  $n$  women. Then there are  $2^n - 1$  nonempty subset for  $W$ . Thus, Hall's Marriage Theorem suggests that we ensure  $|N(S)| \geq |S|$  for every nonempty subset  $S$  of  $W$ . This method has complexity  $O(2^n)$ .

<sup>2</sup> $N(S)$  is the neighbourhood set of all vertices adjacent to some vertex in  $S$

## 23.2 Maximum Matching in Bipartite Graphs

**Definitions 23.8.** Let  $M$  be a matching in a graph  $G$  and  $P$  is an augmenting path with respect to  $M$ . Let  $M'$  be set of edge in  $P$  and  $M$ . And  $M''$  be the set of edges in  $P$  and not in  $M$ . Then  $M_1 = (M - M') \cup M''$  is the **matching obtained by augmenting  $M$  along path  $P$** .

**Remark.**  $|M_1| = |M| + 1$

**Theorem 23.9.** Let  $M$  be a a matching of a graph  $G$  that is not maximum, and let  $v$  be a single vertex with respect to  $M$ . Let  $M_1$  denote the mathing obtained by augmenting  $M$  along some augmenting path. If  $G$  contains an augmenting path with respect to  $M_1$  that has  $v$  and an end-vertex, then  $G$  contains an augmenting path with respect to  $M$  that has  $v$  as an end-vertex

**Corollary 23.9.1.** Let  $M$  be a matching of a graph  $G$ . Suppose that  $M = M_1, M_2, \dots, M_k$  is a finite sequence of matchings of  $G$  such that  $M_i$  ( $2 \leq i \leq k$ ) is obtained by augmenting  $M_{i-1}$  along some augmenting path. Suppose  $v$  is a single vertex with respect to  $M$  for which there exists no augmenting path starting at  $v$ . Then  $G$  does not contain an augmenting path with respect to  $M_i$  ( $2 \leq i \leq k$ ) that has  $v$  as an end-vertex.

**Definitions 23.10.** An **alternating tree** with respect to a matching  $M$  is a tree such that every path from it's root are alternating path with respect to  $M$ .

**Algorithm 23.11** (Maximum Matching Algorithm for Bipartite Graphs). .

1.  $i \leftarrow 1$  and  $M \leftarrow M_1$
2. If  $i < p$ , then continue; otherwise stop.
3. If  $v_i$  is matched, then  $i \leftarrow i + 1$  and return to Step 2;  
otherwise,  $v \leftarrow v_i$  and  $Q$  is initialized to contain  $v$  only.
4. (1) For  $j = 1, 2, \dots, p$  and  $j \neq i$ , let  $TREE(v_j) \leftarrow F$ .  
Also,  $TREE(v_j) \leftarrow T$ .  
(2) If  $Q = \phi$ , then  $i \leftarrow i + 1$  and return to Step 2;  
otherwise, delete a vertex  $x$  from  $Q$  and continue.  
(3) (1) Suppose that  $N(x) = \{y_1, y_2, \dots, y_k\}$ . Let  $j \leftarrow 1$ .  
(2) If  $j \leq k$ , then  $y \leftarrow y_j$ ; otherwise return to Step 4.2  
(3) If  $TREE(y) = T$ , then  $j \leftarrow j + 1$  and return to Step 4.3.2.  
Otherwise, continue.  
(4) If  $y$  is incident with a matching edge  $yz$ , then  $TREE(y) \leftarrow T$ ,  
 $TREE(z) \leftarrow T$ ,  $PARENT(y) \leftarrow x$ ,  $PARENT(z) \leftarrow y$  and add  
 $z$  to  $Q$ ,  $j \leftarrow j + 1$  and return to Step 4.3.2. Otherwise,  $y$  is a  
single vertex and continue.  
(5) Use  $PARENT$  to determine the alternating  $v - x$  path  $P'$  in the  
alternating tree. Let  $P$  be the augmenting path obtained from  $P'$   
by adding the path  $x, y$ . Proceed to Step 5
5. Augment  $M$  along  $P$  to obtain a new matching  $M'$ . Let  $M \leftarrow M'$ ,  $i \leftarrow i + 1$ , and return to Step 2.

**Definitions 23.12.** Let  $G$  be a weighted complete bipartite graph with partite sets  $V_1$  and  $V_2$ . A **feasible vertex labeling** is a real function  $l : V(G) \rightarrow \mathbb{R}$  on vertex set of  $G$  such that  $l(v) + l(u) \geq w(vu)$  where  $v \in V_1$  and  $u \in V_2$ .

**Definitions 23.13.** Consider the function  $l : V(G) \rightarrow \mathbb{R}$  such that  $\forall v \in V_1, l(v) = \max\{w(vu) : u \in V_2\}$  and  $\forall u \in V_2, l(u) = 0$ . Then  $l$  is a feasible vertex labeling on  $V(G)$ . And,

$E_l$  is the set of all edge of the weighted complete bipartite graph  $G$  such that  $l(v) + l(u) = w(vu)$ .

$H_l$  is the spanning subgraph of  $G$  induced by the edge set  $E_l$ .

**Theorem 23.14.** Let  $l$  be a feasible vertex labeling of a weighted complete bipartite graph  $G$ . If  $H_l$  contains a perfect matching  $M'$ , then  $M'$  is a maximum weight matching of  $G$ .

**Algorithm 23.15** (Kuhn-Munkres). .

1. (1) For each  $v \in V_1$ , let  $l(v) \leftarrow \max\{w(vu) : u \in V_2\}$ .  
 (2) For each  $u \in V_2$ , let  $l(u) \leftarrow 0$ .  
 (3) Let  $H_l$  be the spanning subgraph of  $G$  with edge set  $E_l$ .  
 (4) Let  $G_l$  be the underlying graph of  $H_l$ .
2. Apply Algorithm 23.11 to determine a maximum matching  $M$  in  $G_l$ .
3. (1) If every vertex  $v$  of  $V_1$  is matching with respect to  $M$ , output  $M$  and stop. Otherwise, continue.  
 (2) Let  $x$  be the first single vertex of  $V_1$ .  
 (3) Construct an alternating tree with respect to  $M$  that is rooted at  $x$ . If an augmenting path  $P$  is discovered, then augmenting  $M$  along  $P$  and return to Step 3.1. Otherwise, let  $T$  be the alternating tree with respect to  $M$  and rooted at  $x$  that cannot be expanded further in  $G_l$ .
4. Compute  $m_l \leftarrow \min\{l(v) + l(u) - w(vu) : v \in V_1 \cap V(T), u \in V_2 - V(T)\}$ .  
 Let

$$l'(v) = \begin{cases} l(v) - m_l & \text{for } v \in V_1 \cap V(T) \\ l(v) + m_l & \text{for } v \in V_2 \cap V(T) \\ l(v) & \text{otherwise} \end{cases}$$

5. Let  $l \leftarrow l'$ , construct  $G_l$  and return to Step 3.3.

## 23.4 Factorizations

**Definitions 23.16.** A **factor** of a graph  $G$  is a spanning<sup>3</sup> subgraph of  $G$ .

**Definitions 23.17.** Let  $G_1, G_2, \dots, G_n$  be edge-disjoint factors of  $G$  such that  $E(G) = \cup_{i=1}^n E(G_i)$ . Then  $G$  is **factorable** and  $G = G_1 \oplus G_2 \oplus \dots \oplus G_n$ .

<sup>3</sup>Spanning subgraph of a graph  $G$  has every vertex of  $G$

**Definitions 23.18.** An  $r$ -regular factor of  $G$  is an  **$r$ -factor** of  $G$ .

**Definitions 23.19.** If  $G$  has a factorisation to  $r$ -factors, then  $G$  is  **$r$ -factorable**.

**Remark.**  $K_{3,3}$  is 1-factorable.  $K_5$  is 2-factorable.

**Definitions 23.20.** An **odd component of  $G$**  is a component of  $G$  with odd number of vertices. And an **even component of  $G$**  is a component of  $G$  of with even number of vertices.

**Theorem 23.21** (Tutte). A nontrivial graph  $G$  has a 1-factor iff for every proper subset  $S$  of  $V(G)$ , the number of odd components of  $G - S$  does not exceed  $|S|$ .

**Remark.** There exist cubic graphs that doesn't have a 1-factor.

**Theorem 23.22** (Petersen). Every bridgeless cubic graph contains a 1-factor.

**Remark.** Every bridgeless cubic graphs has a 1-factor. Let  $G$  be a bridgeless cubic graph. Consider every pair of factors  $G_1, G_2$  such that  $G = G_1 \oplus G_2$  where  $G_1$  is a 1-factor and  $G_2$  is a 2-factor.  $G$  is not 1-factorable only if every such  $G_2$  doesn't have a 1-factor.

**Theorem 23.23.** Petersen graph is not 1-factorable.

**Theorem 23.24.** Every  $r$ -regular bipartite multigraph ( $r \geq 1$ ) is 1-factorable.

**Remark** (Application of 1-factorisation). For even number  $p$ , a 1-factorisation of  $K_p$  corresponds to the schedule of a round of the round robin tournament among  $p$  teams. If  $p$  is odd, consider  $K_{p+1}$  where  $v_{p+1}$  is an imaginary team called bye team. A game with bye team is a bye.

**Definitions 23.25.** A **hamiltonian cycle** is a spanning cycle. And, **Hamiltonian graph** is a graph containing a hamiltonian cycle.

**Theorem 23.26.** Complete graph  $K_{2n+1}$  can be factored into  $n$  hamiltonian cycles.

**Remark.** For  $n = 3$ ,  $K_7$  can be factored into three hamiltonian cycles.

**Theorem 23.27.** Let  $0 \leq r < p$ . Then there exists an  $r$ -regular graph of order  $p$  iff  $pr$  is even.

**Definitions 23.28.** Let  $\{E_1, E_2, \dots, E_n\}$  be partition of  $E(G)$ . And let  $H_i$  be subgraph of  $G$  induced by the edge set  $E_i$ . A **decomposition** of a graph  $G$  is a collection of these subgraphs  $H_1, H_2, \dots, H_n$ . And  $G = H_1 \oplus H_2 \oplus \dots \oplus H_n$ .

**Definitions 23.29.** Let  $G = H_1 \oplus H_2 \oplus \dots \oplus H_n$  be a decomposition of  $G$  such that  $H \cong H_i$ . Then  $G$  is  **$H$ -decomposable**.

**Remark.**  $K_{3,3}$  is  $3K_2$ -decomposable.  $K_5$  is  $C_5$ -decomposable.  $K_{2n}$  is  $nK_2$ -decomposable.  $K_{2n+1}$  is  $C_{2n+1}$ -decomposable. Every graph is  $K_2$ -decomposable. Every complete bipartite graph  $K_{m,n}$  is  $K_{1,m}$ -decomposable and  $K_{1,n}$ -decomposable.

## 23.5 Block Designs

**Definitions 23.30.** A block design on a set  $V$  is a collection of  $k$ -element subsets of  $V$  such that each element of  $V$  appears exactly in  $r$  subsets.

**variety** The elements of  $V$  are called varieties.

**block**  $k$ -element subsets of  $V$  are called blocks.

**balanced design** If each variety appears in exactly  $r$  blocks and each pair of varieties appears in exactly  $\lambda$  blocks.

**incomplete design** If blocks are proper subsets of  $V$ . ie,  $k < v$ .

**Definitions 23.31.** A balanced incomplete block design of  $v$  varieties in  $b$  blocks of cardinality  $k$  such that each variety appears in exactly  $r$  blocks and each pair of varieties appears in exactly  $\lambda$  blocks is a  $(b, v, r, k, \lambda)$ -design.

**Theorem 23.32.**  $bk = vr$

**Theorem 23.33.**  $\lambda(v-1) = r(k-1)$

**Corollary 23.33.1.**  $\lambda < r$

**Theorem 23.34** (Fisher's Inequality).  $b \geq v$

**symmetric design** If  $b = v$

**Theorem 23.35.** In a symmetric  $(b, v, r, k, \lambda)$ -design with even  $v$ ,  $r - \lambda$  is a perfect square.

**steiner triple system**  $(b, v, r, k, \lambda)$ -design with  $k = 3$ ,  $\lambda = 1$ .

**Remark.**  $(b, v, r, k, \lambda)$ -designs are incomplete. However, a complete block design (ie,  $v = 3$ ) is also included as a Steiner triple system.

**Theorem 23.36.** Steiner triple system with  $v$  varieties exists iff  $v = 6n + 1$  or  $v = 6n + 3$  or  $v = 3$ .

**Definitions 23.37** (Kirkman's Schoolgirls Problem). A class of 15 girls. Parade 15 girls in five rows (3 girls in a row). Is it possible to plan 7 days parade so that two girls are together in a row exactly once ?

**kirkman triple system** Steiner triple system with  $v = 6n + 3$ .

**Remark.** It is proved that kirkman triple system exists with  $v = 6n + 3$  for every  $n \geq 0$ .

**Theorem 23.38.** The code consisting of the rows of the incidence matrix of a  $(b, v, r, k, \lambda)$ -design ( $b = v$ ,  $r=k$ ) is  $t$ -error correcting, where  $t = k - \lambda - 1$ .

# Bibliography

- [apo, 1973] (1973). *Mathematical Analysis, 2nd edition*. Narosa Publishing House.
